# exit

Quit the CLI session

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **exit** command ends the current CLI session.

## Examples

The following example ends the current CLI session:

```
cluster1::> exit
Goodbye
```

# history

Show the history of commands for this CLI session

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **history** command displays the command history of the current CLI session. A numeric ID precedes each command. Use this number with the [redo](#) command to re-execute that history item.

## Examples

The following example displays the command history of the current CLI session:

```
cluster1::> history
 1 vserver show
 2 man volume show
 3 volume delete -vserver vs0 -volume temporary2
 4 volume modify { -volume temp* } -state offline
cluster1::> redo 3
```

## Related Links

- [redo](#)

## man

Display the online manual pages

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **man** command displays the manual page of the command you specify. If you do not specify a command, command displays the man page index.

## Parameters

[<text>] - Valid CLI command

The command for which you'd like to see the manual page. The syntax of the command is the same as the command itself. The **man** command supports abbreviations and tab completion of the command name.

## Examples

The following example displays the manual page for the **storage aggregate create** command.

```
cluster1::> man sto aggr cre
```

That example could also have been fully specified as:

```
cluster1::> man storage aggregate create
```

## redo

Execute a previous command

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **redo** command re-executes a command that has been executed previously in the current CLI session. Specify a previously run command using:

- A string that matches part of a previous command. For example, if the only **volume** command you have run is **volume show**, enter `redo``vol` to re-execute the command.
- The numeric ID of a previous command, as listed by the [history](#) command. For example, enter `redo``4` to re-execute the fourth command in the history list.
- A negative offset from the end of the history list. For example, enter `redo``-2`` to re-execute the command that you ran two commands ago.

## Parameters

[<text>] - String, Event Number, or Negative Offset

Use this parameter to specify a string, a numeric ID from the command history, or a negative number that identifies the command to be re-executed.

## Examples

The following example re-executes command number 10 in the command history:

```
cluster1::> redo 10
```

## Related Links

- [history](#)

## rows

Show/Set the rows for the CLI session

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **rows** command displays the number of rows that can be displayed in the current CLI session before the interface pauses output. If you do not set this value, it adjusts automatically based on the actual height of your terminal. If the actual height is undefined, the default number of rows is 24.

Specify a number to set the number of rows that can be displayed. Setting this value manually disables auto-adjustment. Specify zero (0) to disable pausing.

You can also set this value using the `set -rows` command.

## Parameters

### [<integer>] - Number of Rows the Screen Can Display

Use this parameter to specify the number of rows your terminal can display.

## Examples

The following example displays the current number of rows, then resets the number of rows to 48:

```
cluster1::> rows
36

cluster1::> rows 48
```

## Related Links

- [set](#)

## set

Display/Set CLI session settings

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `set` command changes attributes of the user interface.

## Parameters

### [-privilege <PrivilegeLevel>] - Privilege Level

Use this parameter to specify the privilege level of the command session. Possible values are

- `admin` - Used for routine system management commands
- `advanced` - Used for infrequent, dangerous, or complicated commands
- `diagnostic` - Used for detailed diagnostic commands that are used only by support personnel

### [-confirmations {on|off}] - Confirmation Messages

Use this parameter with the value `on` to specify that the interface prompt for confirmation before executing potentially dangerous commands. Use this parameter with the value `off` to specify that the interface not prompt for confirmation, even before potentially dangerous commands execute.

The default setting is **on** .

### **[-showallfields {true|false}] - Show All Fields**

Use this parameter with the value **true** to specify that the interface display all field columns when displaying tabular output. Use this parameter with the value **false** to specify that the interface display only selected columns. The default setting is **false** .

### **[-showseparator <text>] - Show Separator**

Use this parameter to specify the characters to use as the field separator. The field separator is used between field columns when **-showallfields** is set to "true". The separator can be from one to three characters in length. When specifying the separator, enclose it in quotation marks ( " ). Set the separator to one or more spaces to disable this feature.

### **[-active-help {true|false}] - Active Help**

Use this parameter with the value **true** to specify that pressing the question mark ( ? ) key is sufficient to execute a help request. Use this parameter with the value **false** to specify that you must press the Return key after the question mark key to execute a help request. The default setting is **true** .

### **[-units {auto|raw|B|KB|MB|GB|TB|PB}] - Data Units**

Use this parameter to specify the default units used when reporting data sizes. Possible values are:

- **auto** - Auto-scale data size for human-readable output
- **raw** - Bytes without unit designation
- **B** - Bytes
- **KB** - Kilobytes (1024 bytes, aka kibibytes)
- **MB** - Megabytes (KB x 1024, aka mebibytes)
- **GB** - Gigabytes (MB x 1024, aka gibibytes)
- **TB** - Terabytes (GB x 1024, aka tebibytes)
- **PB** - Petabytes (TB x 1024, aka pebibytes)

The default setting is **auto** .

### **[-rows <integer>] - Pagination Rows ('0' disables)**

Use this parameter to specify the number of rows that can be displayed in the current CLI session before the interface pauses output. If you do not set this value, it adjusts automatically based on the actual height of your terminal. If the actual height is undefined, the default number of rows is 24.

Setting this value manually disables auto-adjustment. Specify zero ( 0 ) to disable pausing.

You can also set this value using the rows command.

### **[-vserver <text>] - Default Vserver**

Use this parameter to specify the name of the Vserver to use as the default value for the **-vserver**

parameter of commands.

Vserverized commands that only have a single required parameter, which is the `<userinput>-vserver<userinput>`, allow the Vserver to be specified positionally, without `<userinput>-vserver<userinput>` preceding it. Due to this, care must be taken when using CLI commands that do not require the `<userinput>-vserver<userinput>` parameter. For example, using the "vserver nfs delete " **command will ignore the "set -vserver" value as the parser considers the "" to be the Vserver.**

### `[-node <text>] - Default Node`

Use this parameter to specify the name of the node to use as the default value for the `-node` parameter of commands.

### `[-stop-on-error {true|false}] - Stop On Error`

Use this parameter with the value `true` to specify that continuing commands should stop if they encounter an error. Use this parameter with the value `false` to specify that continuing commands should continue if they encounter an error.

### `[-prompt-timestamp {above|inline|none}] - Display Prompt Timestamp`

Print the current date and time as a part of the prompt. The possible values are

- **above** - print the timestamp using the system timestamp format on the line above the remainder of the prompt.
- **inline** - print the timestamp using the system timestamp format at the beginning of the line with the remainder of the prompt.
- **none** - do not print the timestamp.

The default value is `none`.

## Examples

The following example sets the privilege level to advanced.

```
cluster1::> set -privilege advanced
```

```
Warning: These advanced commands are potentially dangerous; use them only when
        directed to do so by Fujitsu personnel.
```

```
Do you wish to continue? (y or n): y
```

```
cluster1::*>
```

The following examples cause all columns to be shown in output rows, with a comma used as the field separator.

```
cluster1::> set -showallfields true
```

```

cluster1::> set -showseparator ","

## Related Links

- [rows](#)

## top

Go to the top-level directory

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **top** command changes the current working directory of the command prompt to the top-level command directory.

## Examples

The following example returns the command prompt from the **storage aggregate** directory to the top-level directory:

```
cluster1::storage aggregate> top  
  
cluster1::>
```

## up

Go up one directory

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **up** command, which can also be specified as two dots (**..**), changes the current working directory of the command prompt to the directory that is up one level in the command hierarchy.

## Examples

The following example takes the command prompt up one level from the **storage aggregate** directory:

```
cluster1::storage aggregate> up  
  
cluster1::storage>
```

# application provisioning config modify

Modify options for application provisioning

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command modifies the options for application provisioning operations.

## Parameters

### `[-is-mixed-storage-services-allowed {true|false}] - Is Mixed Storage Services Allowed`

Specifies whether mixed cost storage services are allowed for provisioning placement. If the value of this parameter is **false**, only the aggregates closest to the performance requirements of the storage service are used. If the value of this parameter is **true**, all aggregates with sufficient performance are considered. The initial value for option is **false**.

## Examples

```
cluster1::*> application provisioning config modify -is-mixed-storage-services-allowed true
```

Enables the use of mixed storage services for provisioning placement.

# application provisioning config show

Display options for application provisioning

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command displays options for application provisioning.

## Examples

```
cluster1::*> application provisioning config show  
Is Mixed Storage Services Allowed: false
```

# autobalance aggregate show-aggregate-state

Display the Auto Balance Aggregate state for an aggregate

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **autobalance aggregate show-aggregate-state** command displays information about an aggregate state that is considered by the Auto Balance Aggregate feature.

## Parameters

**{ [-fields <fieldname>, ...]**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[-instance ]}**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node Name**

If this parameter is specified, the display will be limited to only those aggregates with a node that matches the specified value.

**[-aggregate <aggregate name>] - Name of the Aggregate**

If this parameter is specified, the display will be limited to only that aggregate with a name that matches the specified value.

**[-total-size {<integer>[KB|MB|GB|TB|PB]}] - Total Size of the Aggregate**

If this parameter is specified, the display will be limited to only those aggregates with a total-size that matches the specified value.

**[-used-size {<integer>[KB|MB|GB|TB|PB]}] - Used Size of the Aggregate**

If this parameter is specified, the display will be limited to only those aggregates with a used-size that matches the specified value.

**[-aggregate-unbalanced-threshold {<integer>[KB|MB|GB|TB|PB]}] - Threshold When Aggregate Is Considered Unbalanced**

If this parameter is specified, the display will be limited to only those aggregates with a threshold that matches the specified value.

**[-outgoing-size {<integer>[KB|MB|GB|TB|PB]}] - Size of Outgoing Volumes in the Aggregate**

If this parameter is specified, the display will be limited to only those aggregates with an outgoing-size that matches the specified value. Outgoing size will be equal to the total size of the volumes that move away from each one of those aggregate.

**[-incoming-size {<integer>[KB|MB|GB|TB|PB]}] - Size of Incoming Volumes in the Aggregate**

If this parameter is specified, the display will be limited to only those aggregates with an incoming-size that matches the specified value. Incoming size will be equal to the total size of the volumes that move towards to each one of those aggregates.

**[-raidtype {raid\_tec|raid\_dp|raid4|raid\_ep}] - RAID Type**

If this parameter is specified, the display will be limited to only those aggregates with a raidtype that matches the specified value.

**[-home-cluster <UUID>] - Home Cluster ID**

If this parameter is specified, the display will be limited to only those aggregates with a home-cluster ID that matches the specified value.

**[-is-hybrid {true|false}] - Aggregate Is a Hybrid**

If this parameter is specified as true, the display will be limited to only hybrid aggregates. If the parameter is specified as false, the display will be limited to only non-hybrid aggregates.

**[-is-incoming-volume-thin {true|false}] - An Incoming Volume Is Thin**

When you use thin provisioning for a volume, it can run out of space even if it has not yet consumed its nominal size and you should carefully monitor space utilization to avoid unexpected errors due to the volume running out of space. If this parameter is specified as true, the display will be limited to only those aggregates which are the target of a move of thin volume. If the parameter is specified as false, the display will be limited to only those aggregates which are not the target of a move of thin volume.

**[-is-balanceable {true|false}] - Is Balanceable**

If this parameter is specified as true, the display will be limited to only balanceable aggregates. If the parameter is specified as false, the display will be limited to only non-balanceable aggregates.

**[-is-move-target {true|false}] - Aggregate Is a Volume Move Target**

If this parameter is specified as true, the display will be limited to only those aggregates which are target of a volume move. If the parameter is specified as false, the display will be limited to only those aggregates which are not the target of a volume move.

**[-attributes <text>,...] - Aggregate Attributes**

If this parameter is specified, the display will be limited to only those aggregates with attributes that matches the specified values.

**[-aggregate-available-threshold {<integer>[KB|MB|GB|TB|PB]}] - Threshold When Aggregate Is Considered Balanced**

If this parameter is specified, the display will be limited to only those aggregates which meet the specified threshold to be considered as balanced.

## Examples

The following example displays information about the state for all aggregates in the cluster.

```
cluster1::*> autobalance aggregate show-aggregate-state
      Aggregate: aggr0
      Total Size: 4.78GB
      Used Size: 4.56GB
      Outgoing Size: 0B
```

```

        Incoming Size: 0B
    Aggregate Used Space Threshold: 3.34GB
    Aggregate Available Space Threshold: 1.91GB

```

# autobalance aggregate show-unbalanced-volume-state

Display the Auto Balance Aggregate state for a volume

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `autobalance aggregate show-unbalanced-volume-state` command displays information about a volume that is considered by the Auto Balance Aggregate feature.

## Parameters

`{ [-fields <fieldname>, ... ] }`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

`[ [-instance ] ] }`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-node {<nodename>|local}] - Node Name`

If this parameter is specified, the display will be limited to only those volumes with a node that matches the specified value.

`[-DSID <integer>] - DSID of the Last Volume Queried`

If this parameter is specified, the display will be limited to only those volumes with a DSID that matches the specified value.

`[-aggregate <aggregate name>] - Aggregate`

If this parameter is specified, the display will be limited to only those volumes with an aggregate name that matches the specified value.

`[-volume-name <text>] - Name of the Volume`

If this parameter is specified, the display will be limited to only that volume with a name that matches the specified value.

**[-last-threshold-crossed-time <MM/DD/YYYY HH:MM:SS>] - Last Time Threshold Crossed**

If this parameter is specified, the display will be limited to only those volumes with a threshold crossing time that matches the specified value.

**[-last-placed-time <MM/DD/YYYY HH:MM:SS>] - Last Time Volume Was Moved**

If this parameter is specified, the display will be limited to only those volumes with a last time they have been moved that matches the specified value.

**[-is-moving {true|false}] - Is Volume Currently Moving**

If this parameter is specified as true, the display will be limited to only the moving volumes. If the parameter is specified as false, the display will be limited to only the non-moving volumes.

**[-is-quiesced {true|false}] - Is Volume Quiesced**

If this parameter is specified as true, the display will be limited to only the quiesced volumes. If the parameter is specified as false, the display will be limited to only the non-quiesced volumes.

**[-total-footprint {<integer>[KB|MB|GB|TB|PB]}] - Total Size of the Volume**

If this parameter is specified, the display will be limited to only those volumes with a total footprint that matches the specified value.

**[-attributes <text>,...] - Volume's Attributes**

If this parameter is specified, the display will be limited to only those volumes with attributes that matches the specified value.

**[-last-checked <MM/DD/YYYY HH:MM:SS>] - Last Time Volume State Was Checked**

If this parameter is specified, the display will be limited to only those volumes with a last time their state was checked that matches the specified value.

## Examples

The following example display information about all of the unbalanced volumes that the Auto Balance Aggregate feature is aware of.

```
cluster1::*> autobalance aggregate show-unbalanced-volume-state
                Last Checked On: 3/13/2014 14:32:01
Volume: ro10
                Footprint: 20.20MB
Last Time Over IOPS Threshold: 3/12/2014 16:20:18
                Last Placed: 3/11/2014 10:16:04
                Attributes: Over IOPS Threshold
                        Stabilizing
Volume: test
                Footprint: 20.20MB
Last Time Over IOPS Threshold: 3/12/2014 16:20:18
                Last Placed: 3/11/2014 10:16:42
                Attributes: Over IOPS Threshold
                        In Mirror
```

## Stabilizing

The following example displays all of the information that the Auto Balance Aggregate feature has collected for all of the unbalanced volumes it is aware of.

```
cluster1::*> autobalance aggregate show-unbalanced-volume-state -instance
      Node Name: cluster-1-01
DSID of the Last Volume Queried: 1025
      Aggregate: aggr_1
      Name of the Volume: ro10
Last Time Threshold Crossed: 3/12/2014 16:20:18
Last Time Volume Was Moved: 3/11/2014 10:16:04
Is Volume Currently Moving: false
      Is Volume Quiesced: false
      Total Size of the Volume: 20.20MB
      Volume's Attributes: Over IOPS Threshold
                          Stabilizing
Last Time Volume State Was Checked: 3/13/2014 08:20:18
Node Name: cluster-1-01
DSID of the Last Volume Queried: 1026
      Aggregate: aggr_1
      Name of the Volume: test
Last Time Threshold Crossed: 3/12/2014 16:20:18
Last Time Volume Was Moved: 3/11/2014 10:16:42
Is Volume Currently Moving: false
      Is Volume Quiesced: false
      Total Size of the Volume: 20.20MB
      Volume's Attributes: Over IOPS Threshold
                          In Mirror
                          Stabilizing
Last Time Volume State Was Checked: 3/13/2014 08:20:18
```

## autobalance aggregate config modify

Modify the Auto Balance Aggregate feature configuration

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

The **autobalance aggregate config modify** command allows the user to customize the parameters that determine when volumes should be considered for automatic move or recommendation by the Auto Balance Aggregate feature.

## Parameters

### **[-is-enabled {true|false}] - Is the Auto Balance Aggregate Feature Enabled**

This specifies whether the Auto Balance Aggregate feature is enabled and running.

### **[-aggregate-unbalanced-threshold-percent <integer>] - Threshold When Aggregate Is Considered Unbalanced (%)**

This specifies the space used threshold percentage that will cause the Auto Balance Aggregate feature to consider an aggregate as unbalanced.

### **[-aggregate-available-threshold-percent <integer>] - Threshold When Aggregate Is Considered Balanced (%)**

This specifies the threshold percentage which will determine if an aggregate is a target destination for a move. The Auto Balance Aggregate feature will attempt to move volumes from an unbalanced aggregate until it is under this percentage.

## Examples

The following example displays a modification for the default configuration of the Auto Balance Aggregate feature

```
cluster1::*> autobalance aggregate config show
          Is the Auto Balance Aggregate Feature Enabled: false
          Threshold When Aggregate Is Considered Unbalanced (%): 70
          Threshold When Aggregate Is Considered Balanced (%): 40
cluster1::*> autobalance aggregate config modify -is-enabled true
cluster1::*> autobalance aggregate config show
          Is the Auto Balance Aggregate Feature Enabled: true
          Threshold When Aggregate Is Considered Unbalanced (%): 70
          Threshold When Aggregate Is Considered Balanced (%): 40
```

## autobalance aggregate config show

Display the Auto Balance Aggregate feature configuration

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **autobalance aggregate config show** command displays information about parameters that determine when volumes should be considered for automatic move or recommendation by the Auto Balance Aggregate feature.

## Examples

The following example displays the default configuration for the Auto Balance Aggregate feature

```
cluster1::*> autobalance aggregate config show
      Is the Auto Balance Aggregate Feature Enabled: false
      Threshold When Aggregate Is Considered Unbalanced (%): 70
      Threshold When Aggregate Is Considered Balanced (%): 40
```

## cluster add-node-status-clear-failed

Remove failed nodes from the status list

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **cluster add-node-status-clear-failed** command removes failed entries from the status list displayed by the [cluster add-node-status](#) command.

## Examples

The following example removes failed entries:

```
clus1::> cluster add-node-status
      Node Name      Cluster IP      Status      Error Reason
      -----
      -              2.2.2.2       failure     The cluster port MTU
or                                     values do not match.
the                                     Retry cluster create
the                                     join after updating
the                                     cluster port MTUs to
                                         same value.
      node1          1.1.1.1       success
      2 entries were displayed.
clus1::> cluster add-node-status-clear-failed
clus1::> cluster add-node-status
      Node Name      Cluster IP      Status      Error Reason
      -----
      node1          1.1.1.1.       success
```

## Related Links

- [cluster add-node-status](#)

# cluster add-node-status

Show cluster expansion progress

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `cluster add-node-status` command displays the progress of the node joining a cluster initiated by using the `cluster create` command or the `cluster add-node` command

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

**[ -instance ] }**

If you specify the `-instance` parameter, the command displays detailed information about all fields.

**[ -node-uuid <UUID> ] - Node UUID**

Select the node that match the specified node UUID.

**[ -node-name <text> ] - Node Name**

Select the nodes that match the specified node name.

**[ -cluster-ip <IP Address> ] - IP Address of a Cluster Interface of Node**

Select the nodes that match the specified cluster IP.

**[ -status <Cluster Operation Status> ] - The Status of Current Task Being Performed**

Select the nodes that match the specified status. This status shows whether the operation is ongoing or complete with success or failure. The various phases that a node goes through are node-initialization, joining-cluster, service-startup, post-cluster-setup and success or failure.

**[ -failure-msg <text> ] - Error Reason**

Select the nodes that match the specified error string.

**[ -last-updated <MM/DD/YYYY HH:MM:SS> ] - Last Updated**

The date/time stamp of the last update to the status.

## Examples

The following example shows the progress of a node add operation:

```
clus1::> cluster add-node-status
Node Name      Node IP      Status      Error Reason
-----
node1          1.1.1.1     success     -
```

## Related Links

- [cluster create](#)
- [cluster add-node](#)

# cluster add-node

Expand the cluster by discovering and adding new nodes

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **cluster add-node** command discovers and adds new nodes to the cluster. When the **-node-count** parameter is specified, the command attempts to add that many nodes to the cluster. The **-node-ip** parameter can be specified to directly add a node. The **-cluster-ips** parameter can be specified to directly add one or more nodes in parallel. Only one of the **-node-count**, **-node-ip** and **-cluster-ips** parameters can be provided. The [system node show-discovered](#) command displays all the nodes discovered on the local network.

The **node-count** parameter is deprecated and may be removed in a future release of Data ONTAP. Use the **-cluster-ips** parameter instead.

The **node-ip** parameter is deprecated and may be removed in a future release of Data ONTAP. Use the **-cluster-ips** parameter instead.

## Parameters

**{ -cluster-ips <IP Address>, ... - List of Cluster Interface IP Addresses of the Nodes Being Added**

This parameter contains a comma separated list of cluster interface IP addresses of the nodes in the cluster you are creating. All the nodes specified in the list will be added to the cluster.

**| -retry <true> - Retry a failed cluster add-node operation**

Use this parameter to retry the most recently failed **cluster add-node** command with the originally specified parameters. Retry is not supported if the **cluster add-node** command was

originally run with either the **-node-count** or **-node-ip** parameters.

### **| -node-count <integer> - (DEPRECATED)-Number of Nodes Being Added**

Number of nodes to be added to the cluster. If fewer nodes are discovered, all the discovered nodes are added to the cluster and the command will fail since there are fewer nodes than specified. If more nodes are found than the number specified, the command will fail because there is no way to determine which nodes you intend to add to the cluster.

The **-node-count** parameter is supported on non-shared architecture platforms only.

### **| -node-ip <IP Address> - (DEPRECATED)-Cluster IP Address of Node }**

Cluster IP address of the node to add. When this parameter is provided, the command directly adds the node.

### **[-node-names <text>, ...] - List of Node Names**

This parameter contains a comma separated list of node names of all the nodes in the cluster you are creating. The node names must have an one to one correspondence with **-cluster-ips** parameter. The names provided will be used to rename the nodes once they are added to the cluster.

### **[-foreground {true|false}] - Foreground Process**

When set to **false** the command runs in the background as a job. The default is **true**, which causes the command to return after the operation completes.

### **[-allow-mixed-version-join <true>] - Allow a Node At a Different Version to Join Cluster**

This parameter allows nodes with different, but compatible versions of Data ONTAP to be added to the cluster. A Data ONTAP best practice is to add nodes to the cluster that are of the same Data ONTAP version as the nodes in the cluster, but that may not always be possible.

## Examples

The following example adds a node using **-cluster-ips**:

```
cluster1::> cluster add-node -cluster-ips 1.1.1.1, 2.2.2.2
    Use the 'cluster add-node-status' command to see the progress of the add-node
    operation.
```

The following example adds 3 nodes using **-node-count**.

```
cluster1::> cluster add-node -node-count 3
    [Job 22] Job succeeded.
```

# cluster create

Create a cluster

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **cluster create** command creates a cluster with one or more nodes. When the **-node-count** parameter is specified, the command attempts to add that many nodes to the cluster. The **-cluster-ips** parameter can be specified to add one or more nodes in parallel. Only one of the **-node-count** and **-cluster-ips** parameters can be provided.

Note that single-node clusters do not require configuring the cluster network. A cluster network interface must be configured before other nodes can join the cluster.

The **node-count** parameter is deprecated and may be removed in a future release of Data ONTAP. Use the **-cluster-ips** parameter instead.

## Parameters

### **[-license <License Code V2>] - (DEPRECATED)-Base License**

This parameter is deprecated and may be removed in a future release of Data ONTAP.

Use this optional parameter to specify the base license for the cluster. Obtain this value from your sales or support representative.

### **-clustername <text> - Cluster Name**

Use this parameter to specify the name of the cluster you are creating.

- The name must contain only the following characters: A-Z, a-z, 0-9, "-" or "\_".
- The first character must be one of the following characters: A-Z or a-z.
- The last character must be one of the following characters: A-Z, a-z or 0-9.
- The maximum supported length is 44 characters.
- The system reserves the following names: "all", "cluster", "local" and "localhost".

### **[[-cluster-ips <IP Address>, ...] - List of Cluster Interface IP Addresses of the Nodes Being Added**

This parameter contains a comma separated list of cluster interface IP addresses of the nodes in the cluster you are creating. All the nodes specified in the list will be added to the cluster.

**[ [-node-count <integer>] - (DEPRECATED)-Node Count**

Use this parameter to specify the number of nodes in the cluster you are creating.

- **-node-count** parameter is supported on non-shared architecture platforms only.

**[-node-names <text>, ...] - List of Node Names**

This parameter contains a comma separated list of node names of all the nodes in the cluster you are creating. The node names must have an one to one correspondence with **-cluster-ips** parameter. The names provided will be used to rename the nodes once they are added to the cluster.

**[-retry <true> - Retry a failed cluster create operation }**

Use this parameter to retry the most recently failed **cluster create** command with the originally specified parameters. Retry is not supported if the **cluster create** command was originally run with either the **-node-count** or **-node-ip** parameters.

## Examples

The following example creates a cluster named cluster1

```
cluster1::> cluster create -clustername cluster1
```

The following example creates a cluster named cluster1 with node-count 4 on a non-shared architecture platform.

```
cluster1::> cluster create -clustername cluster1 -node-count 4
```

## cluster join

(DEPRECATED)-Join an existing cluster using the specified member's IP address or by cluster name

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command is deprecated and may be removed in a future release of Data ONTAP. Use [cluster add-node](#) from a node in the cluster instead.

The **cluster join** command adds a node to an existing cluster. Use the [cluster create](#) command to create a cluster if one does not already exist.

Note that a cluster network interface must be configured for the cluster before other nodes can join the cluster.

## Parameters

### { **-clusteripaddr <IP Address>** - IP Address of a Cluster Interface from a Node in the Cluster

Use this parameter to specify the IP address of a cluster interface. This must be the IP address of a cluster interface of a node that is already in the cluster. This parameter is mutually exclusive with the **-cluster-name** parameter.

### | **-cluster-name <text>** - (DEPRECATED)-Cluster Name of the Cluster to Join }

Deprecated. Use this parameter to specify the name of an existing cluster to join.

### [**-allow-mixed-version-join <true>**] - Allow a Node at a Different Version to Join Cluster

This parameter allows nodes with different, but compatible versions of Data ONTAP to join the cluster. A Data ONTAP best practice is to join nodes to the cluster that are of the same Data ONTAP version as the nodes in the cluster, but that may not always be possible.

### [**-node-name <text>**] - Name to Use for the Node in the Cluster

This parameter specifies the name that the node will have when we join it to the cluster.

## Examples

The following example joins the local node to a cluster. The IP address 192.0.2.66 is the address of a cluster interface of a node that already belongs to the cluster.

```
node::> cluster join -clusteripaddr 192.0.2.66
```

- [cluster create](#)

# cluster modify

Modify cluster node membership attributes

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **cluster modify** command modifies the cluster attributes of a node, including its eligibility to participate in the cluster.

At the advanced privilege level, you can use the command to specify whether a node holds epsilon. Epsilon is an extra fractional vote that enables quorum to form using slightly weaker requirements. For example, two out of four eligible nodes are sufficient to form quorum if one of those two nodes

holds epsilon.

## Parameters

### **-node {<nodename>|local} - Node**

Use this parameter to specify the name of the node to modify. If you do not specify a node, the command runs on the local node.

### **[-epsilon {true|false}] - Epsilon**

Use this parameter with the value **true** to specify that the node holds Epsilon in the cluster. Use this parameter with the value **false** to specify that the node does not hold Epsilon in the cluster. In a cluster, only one node can be designated as Epsilon at any given time. You can designate a node as Epsilon to add weight to its voting in a cluster with an even number of nodes.

### **[-eligibility {true|false}] - Eligibility**

Use this parameter with the value **true** to specify that the node is eligible to participate in the cluster. Use this parameter with the value **false** to specify that the node is not eligible to participate in the cluster.

If you modify a node as ineligible to participate in the cluster, the command prompts you for confirmation before it runs.

### **[-skip-quorum-check-before-eligible <true>] - Skip Quorum Check Before Setting Node Eligible**

If this parameter is specified, quorum checks will be skipped prior to setting a node eligible. When setting a node to eligible, the operation will continue even if there is a possible data outage due to a quorum issue.

### **[-skip-quorum-check-before-ineligible <true>] - Skip Quorum Check Before Setting Node Ineligible**

If this parameter is specified, quorum checks will be skipped prior to setting a node ineligible. When setting a node to ineligible, the operation will continue even if there is a possible data outage due to a quorum issue.

## Examples

This example modifies a node to make it eligible to participate in the cluster.

```
cluster1::*> cluster modify -node node3 -eligibility true
```

The following example removes epsilon from the node named node0 and adds it to the node named node1:

```
cluster1::*> cluster modify -node node0 -epsilon false
cluster1::*> cluster modify -node node1 -epsilon true
```

# cluster ping-cluster

Ping remote cluster interfaces and perform RPC server check

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **cluster ping-cluster** command probes network connectivity to remote cluster interfaces, and performs an RPC server check.

## Parameters

### **-node <nodename>** - Node

Use this parameter to send the ping from the node you specify.

### **[-use-sitelist {true|false}]** - Use Sitelist for Cluster Interfaces

Use this parameter with the value **true** to specify that the command use the sitelist to determine any incomplete cluster IP information. Use this parameter with the value **false** to specify that the command not use the sitelist.

### **[-skip-rpccheck {true|false}]** - Skip RPC Server Check

Use this parameter with the value **true** to specify that the command not perform the rpcinfo check of remote hosts. Use this parameter with the value **false** to specify that the command perform the rpcinfo check. The rpcinfo check checks the status of the RPC servers on the remote hosts. By default, the rpcinfo check runs on the program number of the portmapper. Use the **-rpc -prognum** parameter to override this default.

### **[-rpc-prognum <integer>]** - RPC Server to Check

Use this parameter to override default behavior and run the rpcinfo check on the program number you specify. By default, the rpcinfo check runs on the program number of the portmapper.

## Examples

The following example shows typical output for this command.

```
cluster1::*> cluster ping-cluster -node node1
Host is node1
Getting addresses from network interface table...
Local = 10.254.231.102  10.254.91.42
Remote = 10.254.42.25   10.254.16.228
Ping status:
....
Basic connectivity succeeds on 4 path(s)
Basic connectivity fails on 0 path(s)
```

```

.....
Detected 1500 byte MTU on 4 path(s):
  Local 10.254.231.102 to Remote 10.254.16.228
  Local 10.254.231.102 to Remote 10.254.42.25
  Local 10.254.91.42 to Remote 10.254.16.228
  Local 10.254.91.42 to Remote 10.254.42.25
Larger than PMTU communication succeeds on 4 path(s)
RPC status:
2 paths up, 0 paths down (tcp check)
2 paths up, 0 paths down (udp check)

```

## cluster remove-node

Remove a node from the cluster

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

The `cluster remove-node` command removes a node from a cluster.

Before you can remove a node from a cluster, you must shut down all of the node's shared resources, such as virtual interfaces to clients. If any of a node's shared resources are still active, the command fails. The failure message will display which active resources must be shut down before the node can be removed from the cluster.

### Parameters

**{ -node <nodename> - Node to Unjoin**

Use this parameter to specify the name of the node to remove from the cluster.

**[ -cluster-ip <IP Address> - IP Address of a Cluster Interface of Node to Unjoin }**

Use this parameter to specify the cluster IP of the node to remove from the cluster.

**[-skip-quorum-check-before-unjoin <true>] - Skip Quorum Check before Unjoin**

If this parameter is specified, quorum checks will be skipped prior to the remove-node command. The operation will continue even if there is a possible data outage due to a quorum issue.

**[-skip-last-low-version-node-check <true>] - Skip the Check That Prevents Unjoining the Last Low Versioned Node**

This parameter allows the node with lowest version of Data ONTAP to be removed from the cluster.

### Examples

The following example shows how to remove the node named **node4** from the cluster.

```
cluster1::*> cluster remove-node -node node4
```

# cluster setup

## Setup wizard

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Use of this command to join a node to an existing cluster is deprecated and might be removed in a future release of Data ONTAP. From a node in the cluster use the [system node show-discovered](#) command and then use the [cluster add-node](#) command.

The **cluster setup** command runs the cluster setup wizard, which can be used to either create a cluster or join a node to an existing cluster. When you run the cluster setup wizard, enter the appropriate information at the prompts. You will be asked to provide the following information to create a cluster:

- Node management interface port, IP address, netmask, default gateway
- Cluster name
- Cluster base license key

This parameter has been deprecated. It may be removed from a future release of Data ONTAP.

- Feature license keys
- Cluster administrator's password
- Cluster management interface port, IP address, netmask, default gateway
- DNS domain names
- Name server IP addresses
- Location

You will be asked to provide the following information to join a cluster:

- Node management interface port, IP address, netmask, default gateway
- Cluster IP address

The cluster management interface is used for managing the cluster. It provides one IP address to manage the cluster and will fail over to another node, if necessary. This is the preferred IP address for managing the cluster, but you can also manage the cluster by logging in to the node management IP address of a node in the cluster. Since the cluster management interface must be able to fail over,

the port role for the interface must be "data" and typically the best choice for an IP address is one on the data network. The node management interface will not fail over, so an IP address on the management network and a port with the role "node management" is the best choice. Alternatively, you can assign an IP address on the data network to the cluster management interface - if that is better in your network topology - but the port must be a data port. The two examples below illustrate the cluster create and cluster join operations, respectively.

## Parameters

## Examples

The following example shows the create option of **cluster setup**.

```
node::> cluster setup
Welcome to the cluster setup wizard.

You can enter the following commands at any time:
  "help" or "?" - if you want to have a question clarified,
  "back" - if you want to change previously answered questions, and
  "exit" or "quit" - if you want to quit the cluster setup wizard.
  Any changes you made before quitting will be saved.

You can return to cluster setup at any time by typing "cluster setup".
To accept a default or omit a question, do not enter a value.

This system will send event messages and periodic reports to Technical
Support. To disable this feature, enter
autosupport modify -support disable
within 24 hours.

Enabling AutoSupport can significantly speed problem determination and
resolution should a problem occur on your system.
For further information on AutoSupport, see:
http://support.netapp.com/autosupport/

Type yes to confirm and continue {yes}: yes

Enter the node management interface port [e0c]:
Enter the node management interface IP address: 192.0.2.66
Enter the node management interface netmask: 255.255.255.192
Enter the node management interface default gateway: 192.0.2.1
The node management interface has been modified to use port e0c with IP address
192.0.2.66.
Use your web browser to complete cluster setup by accessing
https://192.0.2.66

Otherwise, press Enter to complete cluster setup using the command line
interface:
Do you want to create a new cluster or join an existing cluster? {create, join}:
```

```
create
```

```
Do you intend for this node to be used as a single node cluster? {yes, no} [no]:
```

```
Existing cluster interface configuration found:
```

Port	MTU	IP	Netmask
e0a	9000	169.254.21.189	255.255.0.0
e0b	9000	169.254.29.73	255.255.0.0

```
Do you want to use this configuration? {yes, no} [yes]:
```

```
Enter the cluster administrator's (username "admin") password:
```

```
Retype the password:
```

```
Step 1 of 5: Create a Cluster
```

```
You can type "back", "exit", or "help" at any question.
```

```
Enter the cluster name: cluster1
```

```
Creating cluster cluster1
```

```
Starting cluster support services .
```

```
Cluster cluster1 has been created.
```

```
Step 2 of 5: Add Feature License Keys
```

```
You can type "back", "exit", or "help" at any question.
```

```
Enter an additional license key []:
```

```
Step 3 of 5: Set Up a Vserver for Cluster Administration
```

```
You can type "back", "exit", or "help" at any question.
```

```
Enter the cluster management interface port [e0d]:
```

```
Enter the cluster management interface IP address: 192.0.2.60
```

```
Enter the cluster management interface netmask: 255.255.255.192
```

```
Enter the cluster management interface default gateway [192.0.2.1]:
```

```
A cluster management interface on port e0d with IP address 192.0.2.60 has been created. You can use this address to connect to and manage the cluster.
```

```
Enter the DNS domain names: data.example.com
```

```
Enter the name server IP addresses: 192.0.2.147
```

```
DNS lookup for the admin Vserver will use the data.example.com domain.
```

```
Step 4 of 5: Configure Storage Failover (SFO)
```

```
You can type "back", "exit", or "help" at any question.
```

```
SFO is licensed.
```

```
SFO will be enabled when the partner joins the cluster.
```

```
Step 5 of 5: Set Up the Node
```

```
You can type "back", "exit", or "help" at any question.
```

```
Where is the controller located []: Sunnyvale
```

```
Cluster "cluster1" has been created.
```

To complete cluster setup, you must join each additional node to the cluster by running "system node show-discovered" and "cluster add-node" from a node in the cluster.

To complete system configuration, you can use either OnCommand System Manager or the Data ONTAP command-line interface.

To access OnCommand System Manager, point your web browser to the cluster management IP address (<https://192.0.2.60>).

To access the command-line interface, connect to the cluster management IP address (for example, `ssh admin@192.0.2.60`).

```
cluster1::>
```

An example of using 'cluster setup' to join a cluster is shown below.

```
node::> cluster setup
Welcome to the cluster setup wizard.
```

You can enter the following commands at any time:

- "help" or "?" - if you want to have a question clarified,
- "back" - if you want to change previously answered questions, and
- "exit" or "quit" - if you want to quit the cluster setup wizard.

Any changes you made before quitting will be saved.

You can return to cluster setup at any time by typing "cluster setup".  
To accept a default or omit a question, do not enter a value.

This system will send event messages and periodic reports to NetApp Technical Support. To disable this feature, enter `autosupport modify -support disable` within 24 hours.

Enabling AutoSupport can significantly speed problem determination and resolution should a problem occur on your system.  
For further information on AutoSupport, see:  
<http://support.netapp.com/autosupport/>

```
Type yes to confirm and continue {yes}: yes
```

```
Enter the node management interface port [e0c]:
Enter the node management interface IP address: 192.0.2.67
Enter the node management interface netmask: 255.255.255.192
Enter the node management interface default gateway: 192.0.2.1
A node management interface on port e0c with IP address 192.0.2.67 has been created.
```

```
Use your web browser to complete cluster setup by accessing
https://192.0.2.67
```

```
Otherwise, press Enter to complete cluster setup using the command line
interface:
Do you want to create a new cluster or join an existing cluster? {create, join}:
join
Existing cluster interface configuration found:
```

Port	MTU	IP	Netmask
e0a	9000	169.254.31.170	255.255.0.0
e0b	9000	169.254.115.61	255.255.0.0

```
Do you want to use this configuration? {yes, no} [yes]:
Step 1 of 3: Join an Existing Cluster
You can type "back", "exit", or "help" at any question.
Enter the IP address of an interface on the private cluster network from the
cluster you want to join: 169.254.115.8
```

```
Joining cluster at address 169.254.115.8
```

```
This node has joined the cluster cluster1.
Step 2 of 3: Configure Storage Failover (SFO)
You can type "back", "exit", or "help" at any question.
SFO is licensed.
SFO will be enabled when the partner joins the cluster.
Step 3 of 3: Set Up the Node
You can type "back", "exit", or "help" at any question.
This node has been joined to cluster "cluster1".
```

To complete cluster setup, you must join each additional node to the cluster by running "system node show-discovered" and "cluster add-node" from a node in the cluster.

To complete system configuration, you can use either OnCommand System Manager or the Data ONTAP command-line interface.

To access OnCommand System Manager, point your web browser to the cluster management IP address (<https://192.0.2.60>).

To access the command-line interface, connect to the cluster management IP address (for example, `ssh admin@192.0.2.60`).

```
cluster1::>
```

- [cluster add-node](#)

# cluster show

Display cluster node members

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `cluster show` command displays information about the nodes in a cluster.

## Parameters

**{[-fields <fieldname>,...]}**

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

**{[-instance ]}**

If you specify the `-instance` parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node**

Selects the nodes that match this parameter value.

**[-node-uuid <UUID>] - UUID**

Selects the nodes that match this parameter value.

**[-epsilon {true|false}] - Epsilon**

Selects the nodes that match this parameter value. In a cluster, only one node can be designated as Epsilon at any given time. You can designate a node as Epsilon to add weight to its voting in a cluster with an even number of nodes.

**[-eligibility {true|false}] - Eligibility**

Selects the nodes that match this parameter value (true means eligible to participate in the cluster).

**[-health {true|false}] - Health**

Selects the nodes that match this parameter value (true means online).

## Examples

The following example displays information about all nodes in the cluster:

```
cluster1::> cluster show
Node           Health Eligibility
-----
node0         true   true
```

cluster agent connection create

node1	true	true
node2	true	true
node3	true	true

The following example displays information about the node named node1:

```
cluster1::> cluster show -node node1
Node: node1
Eligibility: true
Health: true
```

## cluster agent connection create

Create agent connection

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

Create a websocket connection to an external manager that will be used to monitor this cluster. The external manager will have access to REST APIs and CCMA counters based upon the privilege of the user creating the connection.

### Parameters

**-name <text> - Name**

Specify connection name.

**-destination <text> - Destination URL**

Specify destination URL. For secure websocket, this should be amqpws://<host[:port]>

**[-use-proxy {true|false}] - Use Proxy**

Establish this connection through the HTTP Proxy server associated with this connection's IPspace.

**[-subscribe-address <text>] - Subscribe Address**

AMQP address to which ONTAP will subscribe. Defaults to "ontap.agent.manager".

**[-publish-address <text>] - Publish Address**

AMQP address to which ONTAP will publish. Defaults to "ontap.agent.cluster".

**[-certificate-uuid <UUID>] - Auth Certificate UUID**

Specify uuid of an existing certificate to use for authentication to the destination.

**[-certificate-name <text>] - Auth Certificate Name**

Specify name of certificate to be used for authentication to the destination. If paired with certificate-private-key, it names the new certificate.

**[-csr-url <text>] - Auth CSR URL**

URL to send certificate signing request (CSR) that will be used for authenticating with the destination.

**[-csr-token <text>] - Auth CSR Token**

Token for authenticating with CSR URL. Not audited.

**[-manager-token <text>] - Manager Token**

Specify token supplied by manager application to correlate the connection setup back to the workflow that initiated it.

**[-ip-space <IPspace>] - IPspace for connection**

The IPspace to use for the connection.

**[-idle-timeout <integer>] - Idle Timeout**

AMQP idle timeout. Defaults to 0. If set, the local peer will disconnect if it does not receive AMQP frames within the timeout

**[-address-family {unknown|ipv4|ipv6}] - Address Family**

Specify address family.

**[-auto-delete-error-minutes <integer>] - Auto-delete when disconnected for specified minutes**

Specify time to live in minutes for cloud agent connection in error state. Connection will be deleted if it stays in error state beyond this time.

## Examples

```
cluster-1::> cluster agent connection create -name cloud_agent -destination  
amqpws://manager.example.com
```

# cluster agent connection delete

Delete agent connection

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

Delete the connection to an external manager.

## Parameters

**-name <text> - Name**

Specify connection name.

## Examples

```
cluster-1::> cluster agent connection delete -name cloud_agent
```

# cluster agent connection modify

Modify agent connection

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

Modify agent connection properties.

## Parameters

**-name <text> - Name**

Specify connection name.

**[-destination <text>] - Destination URL**

Specify destination URL. For secure websocket, this should be `amqpws://<host[:port]>`

**[-use-proxy {true|false}] - Use Proxy**

Establish this connection through the HTTP Proxy server associated with this connection's IPspace.

**[-subscribe-address <text>] - Subscribe Address**

AMQP address to which ONTAP will subscribe. Defaults to "ontap.agent.manager".

**[-publish-address <text>] - Publish Address**

AMQP address to which ONTAP will publish. Defaults to "ontap.agent.cluster".

**[-certificate-uuid <UUID>] - Auth Certificate UUID**

Specify uuid of an existing certificate to use for authentication to the destination.

**[-certificate-name <text>] - Auth Certificate Name**

Specify name of certificate to be used for authentication to the destination. If paired with `certificate-private-key`, it names the new certificate.

**[-csr-token <text>] - Auth CSR Token**

Token for authenticating with CSR URL. Not audited.

**[-idle-timeout <integer>] - Idle Timeout**

AMQP idle timeout. Defaults to 0. If set, the local peer will disconnect if it does not receive AMQP frames within the timeout

**[-address-family {unknown|ipv4|ipv6}] - Address Family**

Specify address family.

**[-auto-delete-error-minutes <integer>] - Auto-delete when disconnected for specified minutes**

Specify time to live in minutes for cloud agent connection in error state. Connection will be deleted if it stays in error state beyond this time.

## Examples

```
cluster-1::> cluster agent connection modify -name cloud_agent -destination
amqpwss://new-manager.example.com
```

# cluster agent connection show

Display agent connections

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command displays the connections that have been established to help external managers manage the cluster.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[ [-instance ] ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-name <text>] - Name**

Selects the connections that match the supplied name.

**[-uuid <UUID>] - UUID**

Selects the connections that match the supplied uuid.

**[-destination <text>] - Destination URL**

Selects the connections that match the supplied destination.

**[-state {connecting|connected|error|disabled|partial}] - State**

Selects the connections that match the supplied state. The state can have one of the following values:

- connecting - The agent is in the process of establishing the connection.
- connected - The connection is up and active.
- error - The connection is down due to a problem. See error-message and error-time for details.
- disabled - The connection has been administratively disabled.

**[-use-proxy {true|false}] - Use Proxy**

Establish this connection through an HTTP Proxy server associated with this connection's IPspace

**[-subscribe-address <text>] - Subscribe Address**

AMQP address to which ONTAP will subscribe. Defaults to "ontap.agent.manager".

**[-publish-address <text>] - Publish Address**

AMQP address to which ONTAP will publish. Defaults to "ontap.agent.cluster".

**[-certificate-uuid <UUID>] - Auth Certificate UUID**

Selects the connections that match the supplied certificate-uuid.

**[-certificate-name <text>] - Auth Certificate Name**

Selects the connections that match the supplied certificate-name

**[-csr-url <text>] - Auth CSR URL**

URL to send certificate signing request (CSR) that will be used for authenticating with the destination.

**[-manager-token <text>] - Manager Token**

Selects the connections that match the supplied manager-token.

**[-ip-space <IPspace>] - IPspace for connection**

The IPspace to use for the connection

**[-error-code <integer>] - Last Error Code**

Selects the connections that match the supplied error-code.

**[-error-message <text>] - Last Error Message**

Selects the connections that match the supplied error-message.

**[-error-time <MM/DD/YYYY HH:MM:SS>] - Last Error Time**

Selects the connections that match the supplied error-time.

**[-node <nodename>] - Node owning the connection**

The node owning the connection

**[-msg-recv-total <integer>] - Total messages received from manager**

Total messages received from manager

**[-msg-recv-manifest <integer>] - Total manifest messages received from manager**

Total manifest messages received from manager

**[-msg-recv-baseline-request <integer>] - Total baseline.request messages received from manager**

Total baseline.request messages received from manager

**[-msg-recv-counters-request <integer>] - Total counters.request messages received from manager**

Total counters.request messages received from manager

**[-msg-recv-connection-status <integer>] - Total connection status messages received from manager**

Total connection status messages received from manager

**[-msg-recv-connection-modify <integer>] - Total connection modify messages received from manager**

Total connection modify messages received from manager

**[-msg-recv-unknown <integer>] - Total unknown messages received from manager**

Total unknown messages received from manager

**[-msg-send-total <integer>] - Total messages sent to manager**

Total messages sent to manager

**[-msg-send-manifest-request <integer>] - Total manifest.request messages sent to manager**

Total manifest.request messages sent to manager

**[-msg-send-baseline <integer>] - Total baseline messages sent to manager**

Total baseline messages sent to manager

**[-msg-send-counters <integer>] - Total counters messages sent to manager**

Total counters messages sent to manager

**[-msg-send-connection-status <integer>] - Total connection status messages sent to manager**

Total connection status messages sent to manager

**[-msg-send-errors <integer>] - Total error messages sent to manager**

Total error messages sent to manager

**[-msg-delivery-errors <integer>] - Total errors encountered attempting to send/receive**

Total errors encountered attempting to send/receive

**[-msg-connection-total <integer>] - Total connection attempts**

Total connection attempts

**[-msg-connection-errors <integer>] - Total connection errors**

Total connection errors

**[-msg-transport-errors <integer>] - Total transport errors**

Total transport errors

**[-application <text>] - Client Application**

Selects the connections that match the supplied application.

**[-application-url <text>] - App URL**

Selects the connections that match the supplied application-url.

**[-idle-timeout <integer>] - Idle Timeout**

AMQP idle timeout. Defaults to 0. If set, the local peer will disconnect if it does not receive AMQP frames within the timeout

**[-address-family {unknown|ipv4|ipv6}] - Address Family**

Specify address family.

**[-auto-delete-error-minutes <integer>] - Auto-delete when disconnected for specified minutes**

Specify time to live in minutes for cloud agent connection in error state. Connection will be deleted if it stays in error state beyond this time.

## Examples

```
cluster-1::> cluster agent connection show
Name           Destination           State      Application      Use Proxy
-----
cloudinsights amqpws://172.31.50.251  connected  Cloud Insights  false
```

# cluster contact-info modify

Modify contact information for the cluster

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `cluster contact-info modify` command modifies contact information for the cluster

administrators. If any values contain spaces, you must enclose those values in quotes.

Use the `cluster contact-info show` command to display contact information for the cluster administrators.

## Parameters

### **[-primary-name <text>] - Name of Primary Contact**

Use this parameter to specify the name of the primary contact.

### **[-primary-phone <text>] - Phone Number of Primary Contact**

Use this parameter to specify the phone number of the primary contact.

### **[-primary-alt-phone <text>] - Alternate Phone Number of Primary Contact**

Use this parameter to specify the alternate phone number of the primary contact.

### **[-primary-email <text>] - Email Address or User ID of Primary Contact**

Use this parameter to specify the email address of the primary contact.

### **[-secondary-name <text>] - Name of Secondary Contact**

Use this parameter to specify the name of the secondary contact.

### **[-secondary-phone <text>] - Phone Number of Secondary Contact**

Use this parameter to specify the phone number of the secondary contact.

### **[-secondary-alt-phone <text>] - Alternate Phone Number of Secondary Contact**

Use this parameter to specify the alternate phone number of the secondary contact.

### **[-secondary-email <text>] - Email Address or User ID of Secondary Contact**

Use this parameter to specify the email address of the secondary contact.

### **[-business-name <text>] - Business Name**

Use this parameter to specify the name of the business responsible for this cluster.

### **[-address <text>] - Business Address**

Use this parameter to specify the street address of the business responsible for this cluster.

### **[-city <text>] - City Where Business Resides**

Use this parameter to specify the name of the city in which the business is located.

### **[-state <text>] - State Where Business Resides**

Use this parameter to specify the name of the state or province in which the business is located.

### **[-country <Country Code>] - 2-Character Country Code**

Use this parameter to specify the 2-character country code of the country in which the business is located.

## **[-zip-code <text>] - Postal Code Where Business Resides**

Use this parameter to specify the postal or ZIP code area in which the business is located.

## Examples

The following example changes the name and phone numbers of the secondary contact person for the cluster.

```
cluster1::> cluster contact-info modify -secondary-name "John Doe" -secondary-phone
123.555.0156 -secondary-alt-phone 123.555.0178
```

The following example changes the mailing address of the business responsible for the cluster.

```
cluster1::> cluster contact-info modify -address "123 Example Avenue" -city
Exampleville -state "New Example" -zip-code 99999 -country US
```

## Related Links

- [cluster contact-info show](#)

# cluster contact-info show

Display contact information for the cluster

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **cluster contact-info show** command displays contact information for the cluster administrators.

## Examples

The following example shows example output for this command.

```
cluster1::> cluster contact-info show
Name of Primary Contact : Richard Roe
      Phone Number of Primary Contact : 123.555.0123
      Alternate Phone Number of Primary Contact : 123.555.0145
      Email Address or User Id of Primary Contact : roe@example.com
      Name of Secondary Contact : John Doe
      Phone Number of Secondary Contact : 123.555.0167
      Alternate Phone Number of Secondary Contact : 123.555.0189
      Email Address or User Id of Secondary Contact : doe@example.com
      Business Name : Example Dot Com
```

```
Business Address : 123 Example Avenue
City Where Business Resides : Exampleville
State Where Business Resides : New Example
2-Character Country Code : US
Postal Code Where Business Resides : 99999
```

# cluster controller-replacement network displaced-interface delete

Delete network interfaces displaced away from this node by controller-replacement

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Delete references to logical interfaces that were displaced to another node due to a controller-replacement. A LIF that has been displaced to another node has had its home-node modified to another node because no network ports were available in the same broadcast domain on the original home-node. Deleting this entry does not delete the LIF, it only deletes the entry from the displaced-lifs table indicating that the LIF's current home-node is considered restored.

## Parameters

**-node <nodename> - Node**

Selects the node from which the LIF was displaced.

**-vserver <vserver> - Vserver**

Selects the vserver on which the LIF resides.

**-lif-name <text> - Lif Name**

Selects the name of the LIF for which to display displaced information.

## Examples

The following example deletes displaced LIF information.

```
cluster1::> cluster controller-replacement network displaced-interface delete -vserver
vs0 -lif lif1
```

# cluster controller-replacement network displaced-interface restore-home-node

Restore home node for networked interfaces displaced by controller-replacement

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Restore the original home node of logical interfaces that were displaced to another node due to a controller-replacement. A LIF that has been displaced to another node has had its home-node modified to another node because no network ports were available in the same broadcast domain on the original home-node. Restoring the home-node attempts to find a home-port on the original home node if a suitable port exists.

## Parameters

**-node <nodename> - Node**

Selects the node from which the LIF was displaced.

**-vserver <vserver> - Vserver**

Selects the vserver on which the LIF resides.

**-lif-name <text> - Lif Name**

Selects the name of the displaced LIF to be restored.

## Examples

The following example restores the home-node of a displaced LIF.

```
cluster1::> cluster controller-replacement network displaced-interface restore-home-  
node -vserver vs0 -lif lif1
```

# cluster controller-replacement network displaced-interface show

Display network interfaces displaced away from this node by controller-replacement

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Display logical interfaces that were displaced to another node due to a controller-replacement. A LIF that has been displaced to another node has had its home-node modified to another node because no network ports were available in the same broadcast domain on the original home-node.

## Parameters

{ [-fields <fieldname>, ... ] }

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[ -instance ] }

If you specify the **-instance** parameter, the command displays detailed information about all fields.

[ -node <nodename> ] - **Node**

Selects the node from which the LIF was displaced.

[ -vserver <vserver> ] - **Vserver**

Selects the vserver on which the LIF resides.

[ -lif-name <text> ] - **Lif Name**

Selects the name of the LIF for which to display displaced information.

[ -original-home-node <nodename> ] - **Original Home Node**

The original home-node that was assigned to the LIF prior to controller-replacement.

[ -current-home-node <nodename> ] - **Current Home Node**

The current home-node assigned to the LIF after controller-replacement.

## Examples

The following example displays the displaced LIF information.

```
cluster1::> cluster controller-replacement network displaced-interface show
cluster controller-replacement network displaced-interface show)
original          Current
server            LIF Name                Home Node                Home Node
-----
s0                lif1                     node1                    node2
1 entry was displayed.
```

# cluster controller-replacement network displaced-vlans delete

Remove VLANs displaced by controller-replacement

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Delete VLAN tags that were displaced due to a controller-replacement. A VLAN tag that has been displaced is a tag that was based on a network port that either no longer exists, or was moved to a new broadcast domain. Restoring the `vlan-tags` re-creates them on the specified network port.

## Parameters

**-node <nodename> - Node**

Selects the node on which the displaced vlans reside.

**-port <netport> - Original Base Port**

The original base port where the vlans existed prior to controller-replacement.

## Examples

The following example deletes the displaced vlan-tag information.

```
cluster1::> cluster controller-replacement network displaced-vlans delete -node local  
-port e0c
```

# cluster controller-replacement network displaced-vlans restore

Delete VLANs displaced by controller-replacement

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Restore VLAN tags that were displaced due to a controller-replacement. A VLAN tag that has been displaced is a tag that was based on a network port that either no longer exists, or was moved to a new broadcast domain. Restoring the `vlan-tags` re-creates them on the specified network port.

## Parameters

**-node <nodename> - Node**

Selects the node on which the displaced vlans reside.

**-port <netport> - Original Base Port**

The original base port where the vlans existed prior to controller-replacement.

**-destination-port <netport> - Destination Port**

The destination port where the vlan-tags will be restored.

## Examples

The following example restores vlan-tags displaced from port e0c onto port e0d.

```
cluster1::> cluster controller-replacement network displaced-vlans restore -node node1  
-port e0c -destination-port e0d
```

# cluster controller-replacement network displaced-vlans show

Display VLANs displaced by controller-replacement

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Display VLAN tags that were displaced due to a controller-replacement. A VLAN tag that has been displaced is a tag that was based on a network port that either no longer exists, or was moved to a new broadcast domain. Restoring the vlan-tags re-creates them on the specified network port.

## Parameters

{ [-fields <fieldname>, ...]

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance ]}

If you specify the **-instance** parameter, the command displays detailed information about all fields.

[-node <nodename>] - Node

Selects the node on which the displaced vlans reside.

**[-port <netport>] - Original Base Port**

The original base port where the vlans existed prior to controller-replacement.

**[-vlan-tags <integer>, ...] - Displaced VLANs**

The vlan-tags that were assigned to the network port prior to controller-replacement.

## Examples

The following example displays the displaced vlan-tag information.

```
cluster1::> cluster controller-replacement network displaced-vlans show
cluster controller-replacement network displaced-vlans show)
original
ode      Base Port VLANs
-----
ode1     e0c      100,110,120,300,310,320
1 entry was displayed.
```

# cluster date modify

Modify the current date and time for the nodes in the cluster

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **cluster date modify** command sets the time zone, date, and time on every node in the cluster.

## Parameters

**[-timezone <Area/Location Timezone>] - Time Zone**

This parameter sets the timezone, specified in the Olson format.

**{ [-date {MM/DD/YYYY HH:MM:SS [{+|-}hh:mm]}] - Date and Time**

This parameter sets the date and time, in the format MM/DD/YYYY HH:MM:SS.

**[-dateandtime <[[[[[cc]yy]mm]dd]hhmm[.ss]]>] - Date and Time**

This parameter sets the date and time information, in the format [[[[[cc]yy]mm]dd]hhmm[.ss]].

The argument for setting the date and time is interpreted as follows:

- cc First 2 digits of the year (e.g., 20 for 2011).
- yy Last 2 digits of year (e.g., 10 for 2010).
- mm Numeric month, a number from 01 to 12.
- dd Day, a number from 01 to 31.

- hh Hour, a number from 00 to 23.
- mm Minute, a number from 00 to 59.
- ss Second, a number from 00 to 59.

If the first two digits of the year are omitted, and the last two digits are greater than 68, a date in the 1900s is used. Otherwise, a date in the 2000s is used. If all four digits of the year are omitted, the default is the current year. If the month or day is omitted, the default is the current month or day, respectively. If the seconds are omitted, the default is set to 00. The system automatically handles the time changes for Daylight Saving and Standard time, and for leap seconds and years.

### **[ [-u, -utcdateandtime <[[[[[cc]yy]mm]dd]hhmm[.ss]]>] - UTC Date and Time }**

This parameter sets the date and time information in Coordinated Universal Time (UTC), in the format [[[[[cc]yy]mm]dd]hhmm[.ss]]. -u is an alias for -utcdateandtime. The argument for setting the date and time is interpreted as follows:

- cc First 2 digits of the year (e.g., 20 for 2011).
- yy Last 2 digits of year (e.g., 10 for 2010).
- mm Numeric month, a number from 01 to 12.
- dd Day, a number from 01 to 31.
- hh Hour, a number from 00 to 23.
- mm Minute, a number from 00 to 59.
- ss Second, a number from 00 to 59.

If the first two digits of the year are omitted, and the last two digits are greater than 68, a date in the 1900s is used. Otherwise, a date in the 2000s is used. If all four digits of the year are omitted, the default is the current year. If the month or day is omitted, the default is the current month or day, respectively. If the seconds are omitted, the default is set to 00. Time changes for Daylight Saving and Standard time, and for leap seconds and years, are handled automatically.

## Examples

The following example sets the date and time to January 1 2011, at 1:00 a.m.:

```
cluster1::> cluster date modify -date "01/01/2011 01:00:00"
```

The following example sets the date and time in the UTC format to May 22, 2011, at 09:25:00 a.m.:

```
cluster1::> cluster date modify -u 201105220925.00.
```

## cluster date show

Display the current date and time for the nodes in the cluster

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `cluster date show` command displays the time zone, date, and time settings for one or more nodes in the cluster. By default, the command displays date and time settings for all nodes in the cluster.

## Parameters

**{ [-fields <fieldname>, ... ]**

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

**[ -utc ]**

Displays date and time information in Coordinated Universal Time (UTC).

**[ -utcdate ]**

Displays date and time information in UTC.

**[ -instance ] }**

If you specify the `-instance` parameter, the command displays detailed information about all fields.

**[ -node {<nodename>|local} ] - Node**

Selects the nodes that match this parameter value.

**[ -timezone <Area/Location Timezone> ] - Time Zone**

Selects the nodes that match this parameter value (specified in the Olson format).

**[ -date {MM/DD/YYYY HH:MM:SS [{+|-}hh:mm]} ] - Date and Time**

Selects the nodes that match this parameter value.

**[ -utc-date <MM/DD/YYYY HH:MM:SS> ] - UTC Date and Time**

Selects the nodes that match this parameter value.

**[ -dateandtime <[[[[[cc]yy]mm]dd]hhmm[.ss]]> ] - Date and Time**

Selects the nodes that match this parameter value (interpreted as follows):

- cc First 2 digits of the year (e.g., 20 for 2011).
- yy Last 2 digits of year (e.g., 11 for 2011).
- mm Numeric month, a number from 01 to 12.
- dd Day, a number from 01 to 31.
- hh Hour, a number from 00 to 23.
- mm Minute, a number from 00 to 59.

- ss Second, a number from 00 to 59.

### **[-u, -utcdateandtime <[[[[[cc]yy]mm]dd]hhmm[.ss]]>] - UTC Date and Time**

-u is used as an alias for -utcdateandtime. Selects the nodes that match this parameter value (interpreted as follows):

- cc First 2 digits of the year (e.g., 20 for 2011).
- yy Last 2 digits of year (e.g., 11 for 2011).
- mm Numeric month, a number from 01 to 12.
- dd Day, a number from 01 to 31.
- hh Hour, a number from 00 to 23.
- mm Minute, a number from 00 to 59.
- ss Second, a number from 00 to 59.

## Examples

The following example displays the date and time settings for all nodes in the cluster:

```
cluster1::> cluster date show
Node      Date           Timezone
-----
node0     10/06/2011 09:35:15 America/New_York
node1     10/06/2011 09:35:15 America/New_York
node2     10/06/2011 09:35:15 America/New_York
node3     10/06/2011 09:35:15 America/New_York
4 entries were displayed.
```

## cluster date zoneinfo load-from-uri

Load timezone zoneinfo data

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **cluster date zoneinfo load-from-uri** command loads a new set of timezone zoneinfo data to replace the version installed in the cluster. Releases of Data ONTAP software contain the timezone data that is current at the time of release. If a change is made to the timezone between Data ONTAP releases, then an update can be made to the release data. For instance, if a change is made to when daylight saving time is observed for a country then an update to cluster zoneinfo data may be required.

Only zoneinfo files provided for use in ONTAP should be used with this command.

To update the zoneinfo database do the following:

- Place the file on a local web server accessible without password from the cluster.
- Execute the `cluster date zoneinfo load-from-uri` command, passing the Universal Resource Identifier (URI) of the file as parameter.

The command need only be executed once for the cluster. The data will be distributed to each node of the cluster.

## Parameters

`-uri {(ftp|http|https)://(hostname|IPv4 Address|['IPv6 Address'])...}` - URI of Timezone Zoneinfo Data

URI of the new zoneinfo file.

## Examples

The following example loads a new version of the timezone zoneinfo database to the cluster:

```
cluster1::> cluster date zoneinfo load-from-uri
http://www.example.com/ontap_zoneinfo.zip
```

## cluster date zoneinfo show

Display cluster timezone zoneinfo information

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Display information about the current timezone zoneinfo data.

## Examples

The following example shows the zoneinfo information for a cluster:

```
cluster1::> cluster date zoneinfo show
Cluster Zoneinfo Version: 2016f
```

## cluster ha modify

Modify high-availability configuration of cluster management services

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **cluster ha modify** command enables or disables cluster high availability in a two-node cluster. Enable high availability when performing some procedures, such as replacing hardware.

This command is required to enable high availability if the cluster only has two nodes. Do not run this command in a cluster that has three or more nodes.

Cluster high availability for two-node clusters differs from the storage failover technology used between two nodes for storage high availability.

## Parameters

### **[-configured {true|false}] - HA Configured**

Use this parameter with the value **true** to enable high availability mode in the cluster. Use this parameter with the value **false** to disable high availability mode in the cluster.

## Examples

The following example enables cluster high availability in a cluster.

```
cluster1::> cluster ha modify -configured true
```

## cluster ha show

Show high-availability configuration status for the cluster

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **cluster ha show** command displays the high-availability status of the cluster. Cluster high-availability mode applies only to two-node clusters.

## Examples

The following example displays the high-availability status for a two-node cluster :

```
cluster1::> cluster ha show  
High-Availability Configured: true
```

# cluster identity modify

Modify the cluster's attributes

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `cluster identity modify` command changes a cluster's identity information.

## Parameters

### `[-name <Cluster name>]` - Cluster Name

Use this parameter to specify a new name for the cluster.

- The name must contain only the following characters: A-Z, a-z, 0-9, "-" or "\_".
- The first character must be one of the following characters: A-Z or a-z.
- The last character must be one of the following characters: A-Z, a-z or 0-9.
- The maximum supported length is 44 characters.
- The system reserves the following names: "all", "cluster", "local" and "localhost".

### `[-location <text>]` - Cluster Location

Use this parameter to specify the physical location of the cluster. For example, "Lab 5".

### `[-contact <text>]` - Cluster Contact

Use this parameter to specify contact information for the cluster, such as a name or e-mail address.

## Examples

The following example renames the current cluster to **cluster2** :

```
cluster1::> cluster identity modify -name cluster2
```

## cluster identity show

Display the cluster's attributes including Name, Serial Number, Cluster UUID, Location and Contact

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `cluster identity show` command displays the identity information of the cluster.

## Examples

The following example displays the cluster's UUID, name, serial number, location and contact information:

```
cluster1::> cluster identity show
Cluster UUID: 1cd8a442-86d1-11e0-ae1c-123478563412
      Cluster Name: cluster1
      Cluster Serial Number: 1-80-123456
      Cluster Location: Lab2
      Cluster Contact: jsmith@example.com

cluster1::>
```

## cluster image cancel-update

Cancel an update

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `cluster image cancel-update` command is used to cancel an update that is in either paused-by-user or paused-on-error state. An update can only be canceled if it is in a paused state.

## Examples

The following example displays a cancel-update operation:

```
cluster1::> cluster image cancel-update

Warning: The cancel operation can result in a mixed version
      cluster and/or mixed version HA pair. The cancel
      operation can take several minutes to complete.
Do you want to proceed with the cancel operation? {y|n}: y

Info: Canceling update. It may take a few minutes to finish canceling the update
```

# cluster image pause-update

Pause an update

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **cluster image pause-update** command is used to pause a currently running update. The update pauses at the next predefined pause point (for example, after validation, download to the boot device, takeover completion, or giveback completion) which might take some time to reach. When the update reaches the pause point, it transitions into the pause-by-user state.

## Examples

The following example displays pause-update operation:

```
cluster1::> cluster image pause-update
```

```
Info: Pausing update. It may take a few minutes to finish pausing the update
```

# cluster image resume-update

Resume an update

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **cluster image resume-update** command is used to resume an update that is currently paused in paused-by-user or paused-on-error state. If the update is not paused then an error is returned.

## Parameters

**[-ignore-post-update-checks-failures {true|false}] - Ignore Post-update-checks Phase Failures**

Specifies whether the post update checks phase warnings and/or errors should be ignored. The default value is false.

**[-skip-firmware-update-checks {true|false}] - Skip Firmware Update Status Checks**

Specifies whether firmware update status check will be skipped or not. By default, firmware update status check will not be skipped.

## Examples

The following example shows an resume-update operation:

```
cluster1::> cluster image resume-update
```

```
Info: Resuming update...
```

## cluster image show-update-history

Display the update history

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **cluster image show-update-history** command displays the update history for each node. By default, the command displays the following information:

- Status
- Package version
- Start time
- Completion time
- Component ID
- Previous version
- Updated version

## Parameters

**{ [-fields <fieldname>,...]**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[-instance ]}**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-component-id <text>] - Component ID**

Displays updates for the specified component.

**[-start-time <MM/DD/YYYY HH:MM:SS>] - Start Time**

Displays updates with the specified start time.

**[-package-version <text>] - Package Version**

Displays updates for the specified package version.

**[-status {successful|canceled|back-out}] - Status**

Displays updates that completed with the specified status.

**[-completion-time <MM/DD/YYYY HH:MM:SS>] - Completion Time**

Displays updates with the specified completion time.

**[-previous-version <text>] - Previous Version**

Displays updates with the specified previous version.

**[-updated-version <text>] - Updated Version**

Displays updates with the specified updated version.

## Examples

The following example displays history of automated nondisruptive updates:

```
cluster1::> cluster image show-update-history
Package   Start      Completion
Status    Version    Time        Time        Component ID  Previous  Updated
-----
canceled  8.3        2/11/2014   2/11/2014   ssan-3240-    8.3       8.3
          12:05:51   12:05:51   55a

8 entries were displayed.
```

## cluster image show-update-log-detail

Display detailed information about nondisruptive update events

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `cluster image show-update-log-detail` command displays detailed information about the currently running and previously run nondisruptive update events. By default, the command displays the following information:

- Node
- Transaction ID
- Time stamp
- Destination node
- Task phase
- Task name
- Task status
- Message

## Parameters

**{ [-fields <fieldname>,...]**

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

**[-instance ]}**

If you specify the `-instance` parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node**

Displays information only for the specified node.

**[-task-id <integer>] - Task Id**

Displays information only for the specified task ID.

**[-posted-time <MM/DD/YYYY HH:MM:SS>] - Posted Time**

Displays information that occurred at the specified time.

**[-msg-seq-no <integer>] - Message Sequence**

Displays information only for the specified message sequence number.

**[-current-pid <integer>] - Process ID**

Displays information only for the specified process ID.

**[-destination <text>] - Task Target node**

Displays information only for the specified destination node.

**[-ndu-phase {validation|prereq-updates|ontap-updates|package-management|default-phase|post-update-checks}] - Update phase**

Displays information only for the specified phase.

**[-task-name {initialize|mount-image|restart-hm|get-health|run-scripts|unmount-image|clear-alert|post-restart-hm|cleanup-rd|synch-image|do-download-job|do-failover-job|do-giveback-job|check-progress|complete-validation|invalid-task|default-task|do-postupdate-checks-task}] - Task Name**

Displays information only for the specified task name.

**[-status {created|ready-to-run|running|completed|failed|pause\_req|paused|paused-error|cancel\_req|canceled|resume\_req|default\_status}] - Status Of Task**

Displays information only for items with the specified status.

**[-message <text>] - Update Log Message**

Displays information only for items with the specified message.

**[-msg-type <text>] - Type of Message**

Displays information only for items with the specified message type.

**[-src-info <text>] - Source Information**

Displays information only for items for the specified source.

## Examples

The following example displays detailed information automated nondisruptive updates:

```
cluster1::*> cluster image show-update-log-detail
      Time      Dest      Task  Task  Task
Node  TID Stamp   Node   Phase Name  Status Message

# cluster image show-update-log

Display the update transaction log

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **cluster image show-update-log** command displays detailed information about the currently running, or previously run nondisruptive updates. By default, the command displays the following information:

- Phase
- Transaction
- Transaction ID
- Component ID
- Time stamp
- Status

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**{ [-instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-trans-id <integer>] - Transaction ID**

Displays information for the step associated with the specified transaction ID.

**[-component-id {<nodename>|local}] - Component ID**

Displays information for steps associated with the specified component.

**[-phase {validation|prereq-updates|ontap-updates|package-management|default-phase|post-update-checks}] - Transaction Phase**

Displays information for steps associated with the specified update phase.

**[-trans-name {initialize|mount-image|restart-hm|get-health|run-scripts|unmount-image|clear-alert|post-restart-hm|cleanup-rd|synch-image|do-download-job|do-failover-job|do-giveback-**

**job|check-progress|complete-validation|invalid-task|default-task|do-postupdate-checks-task}] -**

### Transaction Name

Displays information for steps associated with the specified transaction.

**[-timestamp <MM/DD/YYYY HH:MM:SS>] - Timestamp**

Displays information for steps associated with the specified timestamp.

**[-status {waiting|started|completed|paused-on-error|paused-by-user|pause-pending|cancel-pending|canceled|failed}] - Status**

Displays information for steps matching the specified status.

## Examples

The following example displays information about automated nondisruptive update events:

```
cluster1::*> cluster image show-update-log
                    Trans
Phase      Transaction  Id   Component Id      Time Stamp  Status

13 entries were displayed.

## cluster image show-update-progress

Display the update progress

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **cluster image show-update-progress** command displays information about the current state of an update. By default, the command displays the following information:

- Update phase
- Status
- Estimated Duration
- Elapsed Duration

### Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**{ [-instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-ndu-phase {validation|prereq-updates|ontap-updates|package-management|default-phase|post-update-checks}] - Update Phase**

Displays information about the specified update phase.

**[-phase-status {in-progress|waiting|paused-by-user|paused-on-error|completed|canceled|failed|pause-pending|cancel-pending}] - Phase Status**

Displays information about progress matching the specified phase status.

**[-phase-duration <text>] - Phase Duration**

Displays information about progress matching the specified phase duration.

**[-phase-comments <text>] - Phase Comments**

Displays information about progress matching the specified phase comments.

**[-elapsed-duration {<seconds>| [<d> days] <hh>:<mm>[:<ss>]}] - Elapsed duration of the phase**

Displays information about progress matching the specified elapsed duration.

**[-estimated-duration {<seconds>| [<d> days] <hh>:<mm>[:<ss>]}] - Estimated duration of the phase**

Displays information about progress matching the specified estimated duration.

**[-phase-description <text>] - Phase Description**

Displays information about progress matching the specified phase description.

**[-subsystem-name <text>] - Subsystem Name**

Displays information about progress matching the specified subsystem name.

**[-subsystem-status <text>] - Subsystem Status**

Displays information about progress matching the specified subsystem status.

**[-subsystem-details <text>] - Subsystem Details**

Displays information about progress matching the specified subsystem details.

**[-subsystem-action <text>] - Subsystem Action**

Displays information about progress matching the specified subsystem action.

## Examples

The following example shows the automated nondisruptive update of two nodes, nodeA and nodeB. In this case, nodeA's update is waiting, nodeB's update is in progress. nodeB's giveback operation is in progress.

```
cluster1::> cluster image show-update-progress
Estimated      Elapsed
Update Phase   Status          Duration        Duration
-----
Pre-update checks  completed      00:10:00       00:00:02
Data ONTAP updates in-progress    01:23:00       00:32:07

Details:

Node name      Status          Status Description
-----
nodeA          waiting
nodeB          in-progress     Performing giveback operation.
3 entries were displayed.
```

```
cluster1::>
```

The following example shows the automated nondisruptive update of two nodes, nodeA and nodeB. In this case, automated nondisruptive update is paused-on-error in "Data ONTAP updates" phase. nodeA's update is waiting, nodeB's update is failed. "Status Description" show nodeB's error and action.

```
cluster1:> cluster image show-update-progress
Estimated      Elapsed
Update Phase   Status          Duration        Duration
-----
Pre-update checks  completed      00:10:00       00:00:02
Data ONTAP updates  paused-on-error 00:49:00       00:05:21

Details:

Node name      Status          Status Description
-----
nodeA          waiting
nodeB          failed          Error: Takeover of node
               "nodeB" is not possible.
               Action: Use the "storage failover
               show" command to view the cause of
               the failure.

2 entries were displayed.

Status: Paused - An error occurred in "Data ONTAP updates" phase. The
non-disruptive update cannot continue until the error has been resolved.
Resolve all issues, then use the "cluster image resume-update" command to
resume the update.

cluster1:>
```

The following example shows that the automated nondisruptive update is paused-on-error in "Post-update checks" update phase and "Status Description" shows the error and action.

```
cluster1::> cluster image show-update-progress
Estimated      Elapsed
Update Phase   Status          Duration        Duration
-----
Data ONTAP updates  completed      02:19:00       00:00:03
Post-update checks  paused-on-error 00:10:00       00:00:02

Details:

Post-update Check  Status          Error-Action
-----
Cluster Quorum    Error          Error: Cluster is not in quorum.
```

## Status

Action: Use the (privilege: advanced) "cluster ring show" command to verify all replication unit details.

5 entries were displayed.

Status: Paused - An error occurred in "Post-update checks" phase. The non-disruptive update cannot continue until the error has been resolved. Resolve all issues, then use the "cluster image resume-update" command to resume the update.

```
cluster1::>
```

The following example shows that the automated nondisruptive update is completed on nodeA and nodeB.

```
cluster1::> cluster image show-update-progress
Estimated      Elapsed
Update Phase   Status          Duration        Duration
-----
Pre-update checks  completed      00:10:00        00:00:13
Data ONTAP updates completed      01:23:00        01:15:11
Post-update checks completed      00:10:00        00:00:02
3 entries were displayed.

Updated nodes: nodeA, nodeB.
cluster1:>
```

The following example shows the automated update of two-node MetroCluster configuration having clusters cluster\_A and cluster\_B. In this case, cluster\_A's update is waiting and cluster\_B's update is in progress. cluster\_B's switchback operation is in progress.

```
cluster_A::> cluster image show-update-progress
Estimated      Elapsed
Cluster          Duration        Duration        Status
-----
cluster_A          00:00:00        00:00:00        waiting
cluster_B          00:00:00        00:06:42        in-progress

Details: Switchback in progress.

Waiting for partner cluster "sti60-vsimsim-ucs134f_siteB" to be up.

cluster_A::>
```

The following example shows that the automated update is completed on both cluster\_A and cluster\_B in two-node MetroCluster configuration.

```

cluster_A::> cluster image show-update-progress
Estimated      Elapsed
Cluster                Duration      Duration      Status
-----
cluster_A                00:00:00      00:20:44      completed
cluster_B                00:00:00      00:10:43      completed

Details: MetroCluster updated successfully.
cluster_A::>

```

## cluster image show

Display currently running image information

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **cluster image show** command displays information about the version of Data ONTAP that is running on each node and the date/time when it was installed. By default, the command displays the following information:

- Node name
- Current version
- Installation date and time

### Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**{ [-instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node**

Displays information about the specified node.

**[-version <text>] - Current Version**

Displays information about the nodes running the specified version.

**[-date <MM/DD/YYYY HH:MM:SS>] - Date Installed**

Displays information about the nodes with the specified installation date.

## Examples

The following example displays information about currently running images on all nodes of the cluster:

```
cluster1::> cluster image show
      Current          Installation
Node   Version          Date
-----
node1  8.3                -
node2  8.3                -
2 entries were displayed.
```

## cluster image update

### Manage an update

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **cluster image update** command is used to initiate a Data ONTAP update. The update is preceded by a validation of the cluster to ensure that any issues that might affect the update are identified. There are two types of updates of a cluster. A rolling update updates Data ONTAP one HA pair at a time. This type of update is performed for clusters with fewer than eight nodes or when the **-force-rolling** option is specified for clusters with eight or more nodes. A batch update is used for clusters of eight or more nodes, and performs updates of multiple HA pairs at the same time.

There are predefined points in the update when the update can be paused (either by the user or by an error). These pause points occur after validation, after download to the boot device, after takeover has completed, and after giveback has completed.

## Parameters

### **-version <text> - Update Version**

Specifies the Data ONTAP version to use to update the cluster.

### **[-nodes {<nodename>|local}] - Node**

Specifies the nodes that are to be updated. This parameter is not supported for MetroCluster configurations updates or two-stage upgrades. The node upgrade sequence does not follow the node order entered in **cluster image update** command

### **[-estimate-only <>true>] - Estimate Only**

Creates a report of the steps that occur during the update without performing them precisely.

**[-pause-after {none|takeover-giveback|all}] - Update Pause**

Specifies that the update should pause at each predefined pause points (for example, after validation, after download to the boot device, after takeover, and after giveback) during the update.

**[-ignore-validation-warning {true|false}] - Ignore Validation**

Specifies that the update should proceed even if the validation reports warnings.

**[-skip-confirmation {true|false}] - Skip Confirmation**

Specifies that a validation that does not detect any error issues should not ask the user to confirm the update but simply proceed with the update.

**[-force-rolling <true>] - Force Rolling Update**

This option is used for clusters with eight or more nodes to specify that a rolling update (one HA pair at a time) should be done. This parameter is not supported for single-node cluster and two-node MetroCluster.

**[-stabilize-minutes <integer>] - Minutes to stabilize**

Specifies the number of minutes that the update should wait after a takeover or giveback is completed. This allows time for the clients to recover from the pause in I/O that occurs during takeover and giveback. This parameter is not supported for single-node cluster.

**[-show-validation-details <true>] - Shows All Validation Details**

Specify to display all validation details. Default: do not display all details.

## Examples

The following example shows the update operation:

```
cluster1::> cluster image update -version 8.3
```

It can take several minutes to complete validation...

Pre-update Check	Status	Error-Action
CIFS status	OK	
Cluster health status	OK	
Cluster quorum status	OK	
Disk status	OK	
High Availability status	OK	
LIF status	OK	
LIFs on home node status	OK	
MetroCluster configuration status	OK	
SnapMirror status	OK	
Overall Status	OK	

10 entries were displayed.

```
Do you want to continue? {y|n}: y
Starting update...
```

# cluster image validate

Validates the cluster's update eligibility

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `cluster image validate` command checks for issues within the cluster that might lead to problems during the update.

## Parameters

**[-fields <fieldname>,...]**

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

**[-version <text>] - Update Version**

Specifies the Data ONTAP version to use to validate the cluster.

**[-rolling <>true>] - Rolling Update**

Specify this optional parameter on a cluster with eight or more nodes to perform a rolling-update check. The default is to perform a batch-update check.

This parameter is only supported on a cluster with eight or more nodes, and is not supported for two-node MetroCluster.

**[-nodes {<nodename>|local}] - Nodes**

Specifies the nodes that are to be validated. This parameter is not supported for MetroCluster configurations and for two-stage upgrades.

**[-show-validation-details <>true>] - Shows All Validation Details**

Specify to display all validation details. Default: do not display all details.

## Examples

The following example shows the validate operation:

```
cluster1::> cluster image validate -version 8.3
```

It can take several minutes to complete validation...

Pre-update Check	Status	Error-Action
------------------	--------	--------------

```

-----
CIFS status           OK
Cluster health status OK
Cluster quorum status OK
Disk status           OK
High Availability     OK
status
LIF status            OK
LIFs on home node    OK
MetroCluster         OK
configuration status
SnapMirror status     OK
Overall Status       OK
10 entries were displayed.

```

## cluster image package delete

Remove a package from the cluster image package repository

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The `cluster image package delete` command deletes the specified version of the package from the package repository. The associated information about the package is also deleted from the update database.

### Parameters

**-version <text> - Version To Be Deleted**

Specifies the package version that is to be deleted.

### Examples

The following example deletes the package with version 8.3:

```
cluster1::> cluster image package delete -version 8.3
```

```
Package Delete Operation Completed Successfully
```

## cluster image package get

Fetch a package file from a URL into the cluster image package repository

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `cluster image package get` command fetches a Data ONTAP package file specified by the URL into the cluster. The package is stored in the cluster package repository and the information from the package is stored in the update database.

## Parameters

`-url <text>` - Package URL

Specifies the URL from which to get the package.

## Examples

The following example displays how to get a package from a URL:

```
cluster1::> cluster image package get -url http://example.com/image.tgz
```

# cluster image package show-repository

Display information about packages available in the cluster image package repository

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `cluster image package show-repository` command displays the package versions that are in the cluster package repository. By default, the command displays the following information:

- Package version

## Parameters

`{ [-fields <fieldname>, ... ]`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

`[ [-detail ]`

This parameter specifies that detailed information should be displayed.

`[ [-instance ] }`

If you specify the `-instance` parameter, the command displays detailed information about all

fields.

#### **[-download-ver <text>] - Downloaded Version**

Displays packages with the specified download version.

#### **[-component-name <text>,...] - Component Name**

Displays packages for the specified component.

#### **[-component-version <text>,...] - Component Version**

Displays packages with the specified component version.

#### **[-package-build-time <MM/DD/YYYY HH:MM:SS>] - Package Build Time**

Displays packages with the specified build time.

## Examples

The following example displays the packages in the cluster package repository:

```
cluster1::> cluster image package show-repository
Package Version Package Build Time
-----
8.3          9/12/2014 10:27:33
```

## cluster kernel-service show

Display cluster service state in the kernel

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `cluster kernel-service show` command displays the following information from the master node for each node in the cluster:

- Node name
- The quorum status of that node
- The availability status of that node
- The operational status of that node

## Parameters

**{ [-fields <fieldname>,...]**

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the

specified field or fields. You can use '-fields ?' to display the fields to specify.

### **[`-instance` ] }**

If you specify the `-instance` parameter, the command displays detailed information about all fields.

### **[`-master-node` {<nodename>|local}] - Node**

The node in the cluster where the information be being reported from. If this parameter is not specified, the command displays information about all nodes in the cluster.

### **[`-cluster-node` <text>] - Cluster Node**

The node in the cluster that the information listed is regarding. If this parameter is specified, the command displays information only about the nodes with the specified state value.

### **[`-status-quorum` {out-of-quorum|in-quorum}] - Quorum Status**

The quorum status of the node specified by `-cluster-node` . If this parameter is specified, the command displays information only about the nodes with the specified state value.

### **[`-status-avail` {false|true|unknown}] - Availability Status**

The availability status of the node specified by `-cluster-node` . If this parameter is specified, the command displays information only about the nodes with the specified state value.

### **[`-status-oper` {unknown|operational|not-operational}] - Operational Status**

The operational status of the node specified by `-cluster-node` . If this parameter is specified, the command displays information only about the nodes with the specified state value.

## Examples

The following example displays information about all nodes in the cluster:

```
cluster1::*> cluster kernel-service show
Master      Cluster      Quorum      Availability  Operational
Node        Node         Status      Status        Status
-----
cluster1-01 cluster1-01   in-quorum   true          operational
              cluster1-02   in-quorum   true          operational
2 entries were displayed.

cluster1::*> cluster kernel-service show -instance
Master Node: cluster1-01
      Cluster Node: cluster1-01
      Quorum Status: in-quorum
Availability Status: true
Operational Status: operational
Master Node: cluster1-01
      Cluster Node: cluster1-02
      Quorum Status: in-quorum
Availability Status: true
```

Operational Status: operational  
2 entries were displayed.

## cluster kernel-service config modify

Modify cluster service state in the kernel

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

The `cluster kernel-service config modify` used to manage the cluster kernel-service subsystem for a node.

### Parameters

`-node {<nodename>|local}` - Node

The node in the cluster where the configuration is being modified.

`[-kcs-enable-takeover {true|false}]` - Initiated Takeover Enabled

This indicates whether the kernel service subsystem for this node will initiate a takeover of any node determined to be **out of quorum** if allowed by the HA subsystem.

### Examples

```
cluster1::*> cluster kernel-service config modify -node cluster1-01 -kcs-enable-core  
false
```

## cluster kernel-service config show

Display cluster service state in the kernel

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

The `cluster kernel-service config show` is used to display the configuration of the cluster kernel service subsystem for one or more nodes.

### Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**{ [-instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**{ [-node {<nodename>|local}] - Node**

The node in the cluster where the information be being reported from. If this parameter is not specified, the command displays information about all nodes in the cluster.

**{ [-clam-master-id <integer>] - CLAM Master Node ID**

The node ID of the master node for the cluster. If this parameter is specified, the command displays information only about the nodes with the specified state value.

**{ [-kcs-enable-takeover {true|false}] - Initiated Takeover Enabled**

Indicates if the distributed kernel service subsystem will initiate a takeover of any node determined to be **out of quorum** if the HA subsystem allows it. If this parameter is specified, the command displays information only about the nodes with the specified state value.

**{ [-kcs-enabled {true|false}] - KCS Enabled**

The state of the kernel service subsystem on the specified node. If this parameter is specified, the command displays information only about the nodes with the specified state value.

**{ [-quorum-epoch <integer>] - Quorum Epoch**

The number of quorum changes for this node.

## Examples

```
cluster1::*> cluster kernel-service config show
Node                               Failover Core   Master           FSM
          Enabled Enabled Enabled Node           State
-----
cluster1-01      true   false   false   cluster1-01   Master: Waiting for
heartbeat timeout
cluster1-02      true   false   false   cluster1-01   Non-Master: Waiting for
backoff timeout
2 entries were displayed.

cluster1::*> cluster kernel-service config show -instance
Node: cluster1-01
          Master Node: cluster1-01
          Master Node ID: 1000
          Enabled: true
          Initiated Takeover Enabled: false
          Initiated Core on Takeover Enabled: false
```

```

Current FSM State: Master: Waiting for heartbeat timeout
Running Version: 1
  Quorum Epoch: 115
  Voting Status: false
  CHAAQ Enabled: true
Node: cluster1-02
  Master Node: cluster1-01
  Master Node ID: 1000
  Enabled: true
  Initiated Takeover Enabled: false
Initiated Core on Takeover Enabled: false
  Current FSM State: Non-Master: Waiting for backoff timeout
  Running Version: 1
    Quorum Epoch: 115
    Voting Status: false
    CHAAQ Enabled: true

2 entries were displayed.

```

## cluster log-forwarding create

Create a log forwarding destination

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The `cluster log-forwarding create` command creates log forwarding destinations for remote logging.

### Parameters

**-destination <Remote InetAddress> - Destination Host**

Host name or IPv4 or IPv6 address of the server to forward the logs to.

**[-port <integer>] - Destination Port**

The port that the destination server listen on.

**[-protocol {udp-unencrypted|tcp-unencrypted|tcp-encrypted}] - Log Forwarding Protocol**

The protocols are used for sending messages to the destination. The protocols can be one of the following values:

- `_ udp-unencrypted _` - User Datagram Protocol with no security
- `_ tcp-unencrypted _` - Transmission Control Protocol with no security
- `_ tcp-encrypted _` - Transmission Control Protocol with Transport Layer Security (TLS)

**[-ip-space <IPspace>] - IPspace of Destination**

The IPspace of the destination server.

**[-verify-server {true|false}] - Verify Destination Server Identity**

When this parameter is set to **true**, the identity of the log forwarding destination is verified by validating its certificate. The value can be set to **true** only when the **tcp-encrypted** value is selected in the protocol field. When this value is **true** the remote server might be validated by OCSP. The OCSP validation for cluster logs is controlled with the [security config ocsf enable -app audit log](#) and [security config ocsf disable -app audit log](#).

**[-facility <Syslog Facility>] - Syslog Facility**

The syslog facility to use for the forwarded logs.

**[-force <true>] - Skip the Connectivity Test**

Normally, the **cluster log-forwarding create** command checks that the destination is reachable via an ICMP ping, and fails if it is not reachable. Setting this value to **true** bypasses the ping check so that the destination can be configured when it is unreachable.

## Examples

This example causes audit logs to be forwarded to a server at address 192.168.0.1, port 514 with USER facility.

```
cluster1::> cluster log-forwarding create -destination 192.168.0.1 -port 514 -facility user
```

- [security config ocsf enable](#)
- [security config ocsf disable](#)

# cluster log-forwarding delete

Delete a log forwarding destination

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **cluster log-forwarding delete** command deletes log forwarding destinations for remote logging.

## Parameters

**-destination <Remote InetAddress> - Destination Host**

Host name or IPv4 or IPv6 address of the server to delete the forwarding entry for.

**-port <integer> - Destination Port**

The port that the destination server listen on.

## Examples

This example deletes the forwarding of all logs to the server at address 1.1.1.1, port 514.

```
cluster1::> cluster log-forwarding delete -destination 1.1.1.1 -port 514
```

# cluster log-forwarding modify

Modify log forwarding destination settings

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `cluster log-forwarding modify` command modifies log forwarding destinations for remote logging.

## Parameters

**-destination <Remote InetAddress> - Destination Host**

The host name or IPv4 or IPv6 address of the server to be modified.

**-port <integer> - Destination Port**

The port that the destinations servers listen on.

**[-ipSPACE <IPspace>] - IPspace of Destination**

The IPspace of the destination server.

**[-verify-server {true|false}] - Verify Destination Server Identity**

When this parameter is set to **true**, the identity of the log forwarding destination is verified by validating its certificate. The value can be set to **true** only when the **tcp-encrypted** value is selected in the protocol field. When this value is **true** the remote server might be validated by OCSP. The OCSP validation for cluster logs is controlled with the `security config ocsf enable -app audit log` and `security config ocsf disable -app audit log`.

**[-facility <Syslog Facility>] - Syslog Facility**

The syslog facility to use for the forwarded logs.

## Examples

This example modifies the facility of audit logs that are forwarded to the destination server at address 192.168.0.1, port 514.

```
cluster1::> cluster log-forwarding modify -destination 192.168.0.1 -port 514 -facility local1
```

# cluster log-forwarding show

Display log forwarding destinations

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `cluster log-forwarding show` command displays log forwarding information:

- Destination (IPv4/IPv6/hostname)
- Port number
- List of log classes
- Facility

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

**[ -instance ] }**

If you specify the `-instance` parameter, the command displays detailed information about all fields.

**[-destination <Remote InetAddress>] - Destination Host**

If this optional parameter is specified, the command displays information about the forwarding

destinations with the specified host name, IPv4 or IPv6 address.

#### **[-port <integer>] - Destination Port**

If this optional parameter is specified, the command displays information about the forwarding destinations with the specified ports.

#### **[-protocol {udp-unencrypted|tcp-unencrypted|tcp-encrypted}] - Log Forwarding Protocol**

If this optional parameter is specified, the command displays information about the forwarding destinations with the specified protocols.

#### **[-ipSPACE <IPspace>] - IPspace of Destination**

If this optional parameter is specified, the command displays information about the IPspace to which the forwarding destinations belong.

#### **[-verify-server {true|false}] - Verify Destination Server Identity**

If this optional parameter is specified, the command displays information about the forwarding destinations with the specified verify-server values.

#### **[-facility <Syslog Facility>] - Syslog Facility**

If this optional parameter is specified, the command displays information about the forwarding destinations with the specified facility.

## Examples

```
cluster-1::> cluster log-forwarding show
Verify Syslog
Destination Host      Port  Protocol      Server  Facility
-----
192.168.0.1          514   udp-unencrypted false   user
```

## cluster peer create

Create a new cluster peer relationship

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **cluster peer create** command establishes a peer relationship between two clusters. Cluster peering enables independent clusters to coordinate and exchange data.

Before creating a new cluster peer relationship, make sure that both clusters are individually healthy and that there are no other peer relationships between the two clusters that might interfere with the new relationship.

You can create a cluster peer relationship using the IPv4 or IPv6 protocol. You may not use both

protocols within a single relationship.

Use the [cluster show](#) and [cluster peer show](#) commands on each cluster to display health, peering eligibility, and peering information about the two clusters.

## Parameters

### **[-peer-addr <Remote InetAddress>, ...] - Remote Intercluster Addresses**

Use this parameter to specify the names or IP addresses of the logical interfaces used for intercluster communication. Separate the addresses with commas.

The addresses you provide here are associated with the remote cluster until you modify or delete the relationship, regardless of whether the addresses are valid. Make sure to provide addresses which you know will remain available on the remote cluster. You can use the hostnames of the remote cluster's intercluster addresses, the IP addresses of the remote cluster's intercluster LIFs or both.

### **[-username <text>] - Remote User Name**

Use this optional parameter to specify a username that runs a reciprocal **cluster peer create** command on the peered cluster. If you choose not to use the reciprocal creation option, by not supplying a username for reciprocal creation, you must run **cluster peer create** again on the remote cluster to complete the peering relationship.

If you specify the username for the remote cluster, you will be prompted to enter the associated remote password. These credentials are not stored, they are used only during creation to authenticate with the remote cluster and to enable the remote cluster to authorize the peering request. The provided username's profile must have access to the console application in the remote cluster.

Use the [security login role show](#) and [security login show](#) commands on each cluster to find user names and their privilege levels.

### **[-no-authentication <true>] - Do Not Use Authentication**

Use this optional parameter when omitting the **-username** parameter to indicate that you will create an unauthenticated peering relationship.

### **[-timeout <integer>] - Operation Timeout (seconds)**

Use this optional parameter to specify a timeout value for peer communications. Specify the value in seconds. The default timeout value is 60 seconds.

### **[-address-family {ipv4|ipv6}] - Address Family of Relationship**

Use this optional parameter to specify the address family of the cluster peer relationship. The default is based on existing relationships, existing local intercluster LIFs belonging to a particular address-family, and the addresses supplied to the **cluster peer create** command.

### **[-offer-expiration {MM/DD/YYYY HH:MM:SS | {1..7}days | {1..168}hours | PnDTnHnMnS | PnW}] - Passphrase Match Deadline**

Specifying **cluster peer create** normally creates an offer to establish authentication with a cluster

that is a potential cluster peer to this cluster. Such offers expire unless they are accepted within some definite time. Use this optional parameter to specify the date and time at which this offer should expire, the time after which the offer will no longer be accepted.

**[-rpc-connect-timeout <integer>] - Timeout for RPC Connect (seconds)**

Use this optional parameter to specify a timeout value for the RPC connect during peer communications. Specify the value in seconds. The default timeout value is 10 seconds.

**[-update-ping-timeout <integer>] - Timeout for Update Pings (seconds)**

Use this optional parameter to specify a timeout value for pings while updating remote cluster information. Specify the value in seconds. The default timeout value is 5 seconds. This parameter applies only to cluster peer relationships using the IPv4 protocol.

**[-ipspace <IPspace>] - IPspace for the Relationship**

Use this optional parameter to specify the IPspace within which the cluster peering relationship is to operate. The default is to use the 'Default' IPspace.

**[-local-name <Cluster name>] - Peer Cluster Local Name**

Use this optional parameter to specify a unique local name to identify the remote cluster that is being peered. The local name must conform to the same rules as a cluster name. The default value is the remote cluster name.

**[-generate-passphrase <true>] - Use System-Generated passphrase**

Use this optional parameter alone to create cluster peer offer for the unidentified clusters or use it along with **-peer-addrs** option to automatically generate the passphrase for the cluster peer operation with the peer cluster.

**[-initial-allowed-vserver-peers <Vserver Name>, ...] - Vservers allowed for auto peering**

Use this optional parameter to specify the list of Vservers for which reciprocal Vserver peering with peer cluster should be enabled. Upon the time of successful peering, Vserver peer permission entries will be created for the peer cluster for the specified list of Vservers.

**[-encryption-protocol-proposed {none|tls-psk}] - Encryption Protocol To Be Used In Inter-Cluster Communication**

Use this optional parameter to specify how this cluster should use encryption in data connections to the other cluster. Specify 'tls-psk' to specify that TLS should be used with a Pre-Shared Key. Specify 'none' to use no encryption. Where authentication is used, the default is 'tls-psk'. Where authentication is not used, the default is 'none'.

**[-applications {snapmirror|flexcache}] - Peering Applications**

List of peering applications for initially allowed vservers.

## Examples

This example creates a peer relationship between cluster1 and cluster2. This reciprocal create executes the create command on both the local cluster and the remote cluster. The cluster peer create command can use the hostnames of cluster2's intercluster addresses, the IP addresses of

cluster2's intercluster LIFs, or both. Note that the admin user's password was typed at the prompt, but was not displayed.

```
cluster1::> cluster peer create -peer-addr cluster2-d2,10.98.234.246 -username admin

Remote Password:

cluster1::> cluster peer show -instance
Peer Cluster Name: cluster2
    Remote Intercluster Addresses: cluster2-d2, 10.98.234.246
    Availability of the Remote Cluster: Available
        Remote Cluster Name: cluster2
        Active IP Addresses: 10.98.234.246, 10.98.234.243
        Cluster Serial Number: 1-80-123456
    Address Family of Relationship: ipv4
    Authentication Status Administrative: no-authentication
    Authentication Status Operational: absent
        Last Update Time: 02/05 21:05:41
    IPspace for the Relationship: Default
    Encryption for Inter-Cluster Communication: none
```

This example shows coordinated peer creation. The **cluster peer create** command was issued locally on each cluster. This does not require you to provide the username and password for the remote cluster. There is a password prompt, but if you are logged in as the admin user, you may simply press enter.

```
cluster1::> cluster peer create -peer-addr cluster2-d2, 10.98.234.246 -no
-authentication

Remote Password:
NOTICE: Addition of the local cluster information to the remote cluster has
failed with the following error: not authorized for that command. You may
need to repeat this command on the remote cluster.

cluster1::> cluster peer show
Peer Cluster Name      Cluster Serial Number  Availability  Authentication
-----
cluster2              1-80-123456          Available    absent
```

```
cluster2::> cluster peer create -peer-addr cluster1-d2 -no-authentication

Remote Password:
NOTICE: Addition of the local cluster information to the remote cluster has
failed with the following error: not authorized for that command. You may
need to repeat this command on the remote cluster.

cluster2::> cluster peer show
```

cluster peer create

Peer Cluster Name	Cluster Serial Number	Availability	Authentication
cluster1	1-80-654321	Available	absent

This example shows a reciprocal cluster peer create over IPv6 addresses, that establishes a cluster peer relationship with an IPv6 address family.

```
cluster1::> cluster peer create -peer-addr FD20:8B1E:B255:C222:6A17:0BBD:E92C:4523
-username admin

Remote Password:

cluster1::> cluster peer show -instance
Address Family of Relationship: ipv6
        Peer Cluster Name: cluster2
        Remote Intercluster Addresses: FD20:8B1E:B255:C222:6A17:0BBD:E92C:4523
        Availability of the Remote Cluster: Available
        Remote Cluster Name: cluster2
        Active IP Addresses: FD20:8B1E:B255:C222:6A17:0BBD:E92C:4523
        Cluster Serial Number: 1-80-123456
        Address Family of Relationship: ipv6
        Authentication Status Administrative: no-authentication
        Authentication Status Operational: absent
        Last Update Time: 02/05 21:05:41
        IPspace for the Relationship: Default
        Encryption for Inter-Cluster Communication: none
```

This example shows creation of an authenticated peering relationship. It is an example of using the coordinated method to create a cluster peer relationship. The **cluster peer create** command is issued locally on each cluster. Before executing this pair of commands, a passphrase to be used with the commands is chosen and given at the prompts. The passphrase can be any text; it is prompted for twice on each cluster, and all four copies of the passphrase must agree. The passphrase does not echo on the screen. The passphrase must be longer than the minimum length as specified by the **cluster peer policy** on both clusters.

```
cluster1::> cluster peer create -peer-addr cluster2-d2, 10.98.234.246

Enter the passphrase:
Enter the passphrase again:

Notice: Now use the same passphrase in the "cluster peer create" command in the
        other cluster.

cluster1::> cluster peer show
Peer Cluster Name      Cluster Serial Number  Availability  Authentication
-----
cluster2              -                     Unavailable  pending
```

```
cluster2::> cluster peer create -peer-addr cluster1-d2
```

```
Enter the passphrase:
```

```
Enter the passphrase again:
```

```
cluster2::> cluster peer show
```

Peer Cluster Name	Cluster Serial Number	Availability	Authentication
cluster1	1-80-654321	Available	ok

This example creates a peer relationship between cluster1 and cluster2. This reciprocal create executes the create command on both the local cluster and the remote cluster. The cluster peer create command can use the hostnames of cluster2's intercluster addresses, the IP addresses of cluster2's intercluster LIFs or both. Note that the admin user's password was typed at the prompt, but was not displayed. The **-local-name** parameter is specified to create a local name used to identify the peer cluster in cases where the name of the peer cluster is not unique or not descriptive.

```
cluster1::> create -peer-addr 10.98.191.193 -username admin -local-name
locallyUniqueName
```

```
cluster1::> cluster peer show
```

Peer Cluster Name	Cluster Serial Number	Availability	Authentication
locallyUniqueName	1-80-000011	Available	absent

```
cluster1::> cluster peer show -instance
```

```
Peer Cluster Name: locallyUniqueName
    Remote Intercluster Addresses: 10.98.191.193
    Availability of the Remote Cluster: Available
    Remote Cluster Name: cluster2
    Active IP Addresses: 10.98.191.193
    Cluster Serial Number: 1-80-000011
    Address Family of Relationship: ipv4
    Authentication Status Administrative: no-authentication
    Authentication Status Operational: absent
    Last Update Time: 02/05 21:05:41
    IPspace for the Relationship: Default
    Encryption for Inter-Cluster Communication: none
```

The following example create a peer relationship between cluster1 and cluster2 using system-generated passphrases:

```
cluster1::> cluster peer create -peer-addr 10.98.191.193 -generate-passphrase
```

```
Passphrase: UCa+6lRVICXeL/gq1WrK7ShR
```

```
Peer Cluster Name: cluster2
```

```
Initial Allowed Vserver Peers: -
```

```
Expiration Time: 6/7/2017 09:16:10 +5:30
```

```
Intercluster LIF IP: 10.140.106.185
```

Warning: make a note of the passphrase - it cannot be displayed again.

```
cluster1::> cluster peer show
```

Peer Cluster Name	Cluster Serial Number	Availability	Authentication
cluster2	-	Unavailable	pending

```
cluster2::> cluster peer create -peer-addr 10.140.106.185
```

Enter the passphrase:

Clusters cluster1 and cluster2 are peered.

```
cluster2::> cluster peer show
```

Peer Cluster Name	Cluster Serial Number	Availability	Authentication
cluster1	1-80-654321	Available	ok

The following example creates a cluster peer offer from cluster1 for an anonymous cluster using system-generated passphrase with offer expiration period of two days and the cluster2 uses the offer from cluster2 with the system-generated passphrase:

```
cluster1::> cluster peer create -generate-passphrase -offer-expiration 2days
```

```
Passphrase: UCa+6lRVICXeL/gq1WrK7ShR
```

```
Peer Cluster Name: Clus_7ShR (temporary generated)
```

```
Initial Allowed Vserver Peers: -
```

```
Expiration Time: 6/9/2017 08:16:10 +5:30
```

```
Intercluster LIF IP: 10.140.106.185
```

Warning: make a note of the passphrase - it cannot be displayed again.

```
cluster1::> cluster peer show
```

Peer Cluster Name	Cluster Serial Number	Availability	Authentication
Clus_7ShR	-	Unidentified	pending

```
cluster2::> cluster peer create -peer-addr 10.140.106.185
```

Enter the passphrase:

Clusters cluster1 and cluster2 are peered.

```
cluster2::> cluster peer show
```

Peer Cluster Name	Cluster Serial Number	Availability	Authentication
cluster1	1-80-654321	Available	ok

Cluster "cluster1" creates an offer with **initial-allowed-vserver-peers** option set to Vservers "vs1" and "vs2". And the peer cluster "cluster2" uses the offer and creates peer relationship with cluster1, upon the successful peer relationship establishment, Vserver peer permission entries are created for the Vservers "vs1" and "vs2" in cluster "cluster1" for the peer cluster "cluster2". The following example

describes the usage of **initial-allowed-vserver-peers** option in the cluster peer creation workflow:

```
cluster1::> cluster peer create -generate-passphrase -initial-allowed-vserver-peers
vs1,vs2
Passphrase: UCa+6lRVICXeL/gq1WrK7ShR
Peer Cluster Name: Clus_7ShR (temporary generated)
Initial Allowed Vserver Peers: vs1,vs2
Expiration Time: 6/7/2017 09:16:10 +5:30
Intercluster LIF IP: 10.140.106.185
Warning: make a note of the passphrase - it cannot be displayed again.
```

```
cluster1::> cluster peer show
Peer Cluster Name      Cluster Serial Number Availability  Authentication
-----
Clus_7ShR              -                Unidentified  pending
cluster2::> cluster peer create -peer-addr 10.140.106.185
```

Enter the passphrase:

Clusters cluster1 and cluster2 are peered.

```
cluster2::> cluster peer show
Peer Cluster Name      Cluster Serial Number Availability  Authentication
-----
cluster1              1-80-654321      Available  ok
cluster1::> vserver peer permission show
```

```
Peer Cluster      Vserver      Applications
-----
cluster2
                vs1          snapmirror
                vs2          snapmirror
2 entries were displayed.

## cluster peer delete

Delete a cluster peer relationship

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **cluster peer delete** command removes a peering relationship. It removes the relationship records, state data, and all associated jobs.

Before removing the relationship, the command verifies that no resources depend on the relationship. For example, if any SnapMirror relationships exist, the command denies the request to delete the peering relationship. You must remove all dependencies for the deletion to succeed. The **cluster peer delete** command removes only the local instance of the peer relationship. An administrator in the peer cluster must use the **cluster peer delete** command there as well to completely remove the relationship.

## Parameters

### **-cluster <text>** - Peer Cluster Name

Use this parameter to specify the peering relationship to delete by specifying the name of the peered cluster.

## Examples

This example shows a failed deletion due to a SnapMirror dependency.

```
cluster2::> cluster peer delete -cluster cluster1
Error: command failed: Unable to delete peer relationship. Reason: A
SnapMirror source exists in this cluster
```

# cluster peer modify-local-name

Modify the local name for a cluster peer

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **cluster peer modify-local-name** command modifies the local name for a remote cluster. The new local name must be unique among all the local names for the remote clusters with which this cluster is peered.

## Parameters

### **-name <text>** - Cluster Peer Name

Use this parameter to specify the existing local name for a peer cluster.

**-new-name <Cluster name> - Cluster Peer Local Name**

Use this parameter to specify the new local name of the peer cluster. The new local name must conform to the same rules as a cluster name.

## Examples

```
cluster2::> cluster peer modify-local-name -name cluster1 -new-name cluster1A
```

# cluster peer modify

Modify cluster peer relationships

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **cluster peer modify** command modifies the attributes of a peering relationship. When you modify a peer relationship and specify **-peer-addr**s, all of the remote addresses must respond, must be intercluster addresses, and must belong to the remote cluster that is being modified; or the modification request is denied.

## Parameters

**-cluster <text> - Peer Cluster Name**

Use this parameter to specify the peering relationship to modify by specifying the name of the peered cluster.

**[-peer-addr <Remote InetAddress>, ...] - Remote Intercluster Addresses**

Use this parameter to specify the names or IP addresses of the logical interfaces used for intercluster communication. Separate the addresses with commas. The list of addresses you provide replaces the existing list of addresses.

**[-address-family {ipv4|ipv6}] - Address Family of Relationship**

Use this parameter to specify the address family of the names specified with the peer-addr parameter.

**[-timeout <integer>] - Operation Timeout (seconds)**

Use this parameter to specify a timeout value for peer communications. Specify the value in seconds.

**[-auth-status-admin {no-authentication|revoked|use-authentication}] - Authentication Status Administrative**

Use this parameter to adjust the authentication in use for the peer relationship. The defined values for this field are as follows.

- no-authentication - The cluster peer relationship uses no authentication.
- use-authentication - The cluster peer relationship is to be authenticated. After you use this value, you will be prompted for a passphrase to be used in determining a new authentication key, just as in the authenticated `cluster peer create` command or you can use the option `generate-passphrase` to automatically generate the passphrase.
- revoked - The cluster peer relationship is no longer to be trusted. Peering communication with this cluster peer is suspended until the two clusters set their `auth-status-admin` attributes either both to `no-authentication` or both to `use-authentication`.

Changes should be reflected on both clusters involved in a peering relationship.

#### **[-rpc-connect-timeout <integer>] - Timeout for RPC Connect (seconds)**

Use this optional parameter to specify a timeout value for the RPC connect during peer communications. Specify the value in seconds.

#### **[-update-ping-timeout <integer>] - Timeout for Update Pings (seconds)**

Use this optional parameter to specify a timeout value for pings while updating remote cluster information. Specify the value in seconds. This parameter applies only to cluster peer relationships using the IPv4 protocol.

#### **[-ipSPACE <IPspace>] - IPspace for the Relationship**

Use this optional parameter to specify that cluster peering communication for this remote cluster is to be done using local intercluster LIFs that are on ports in the named IPspace.

#### **[-generate-passphrase <true>] - Use System-Generated passphrase**

Use this optional parameter along with `-auth-status-admin` option's `use-authentication` to automatically generate the passphrase which can be used for cluster peer operation.

#### **[-encryption-protocol-proposed {none|tls-psk}] - Encryption For Inter-Cluster Communication**

Use this parameter to adjust the encryption of connections in use for the peer relationship. The defined values for this field are as follows.

- tls-psk - Use TLS with a Pre-Shared Key.
- none - Use no encryption.

## Examples

This example modifies the peering relationship to use a new IP address in the remote cluster for intercluster communications and revoke authentication.

View existing cluster peer configuration using following command :

```
cluster1::> cluster peer show -instance
Peer Cluster Name: cluster2
      Remote Intercluster Addresses: cluster2-d2, 10.98.234.246
      Availability of the Remote Cluster: Available
      Remote Cluster Name: cluster2
```

```

Active IP Addresses: 10.98.234.246, 10.98.234.243
Cluster Serial Number: 1-80-123456
Remote Cluster Nodes: cluster2-01, cluster2-02
Remote Cluster Health: true
Unreachable Local Nodes: -
Address Family of Relationship: ipv4
Authentication Status Administrative: use-authentication
Authentication Status Operational: ok
Last Update Time: 02/05 21:05:41
IPspace for the Relationship: Default
Encryption for Inter-Cluster Communication: tls-psk

```

Modify the cluster peer configuration using following command :

```

cluster1::> cluster peer modify -cluster cluster2 -peer-addr cluster2-
d2,10.98.234.264 -auth-status-admin revoked
Warning: This will discard the authentication key.

```

Warning: You are removing authentication from the peering relationship with cluster "cluster2". Use the "cluster peer modify" command on cluster "cluster2" with the "-auth-status-admin no-authentication" parameter to complete authentication removal from the peering relationship.

```

Do you want to continue?{y|n}:y

```

The following example modifies the peering relationship to use authentication with **-generate-passphrase** option.

```

cluster1::> cluster peer modify -cluster cluster2
-auth-status-admin use-authentication -generate-passphrase

```

Notice: Use the below system-generated passphrase in the "cluster peer modify" command in the other cluster.

```

Passphrase: UCa+6lRVICXeL/gq1WrK7ShR
Expiration Time: 6/7/2017 09:16:10 +5:30
Peer Cluster Name: cluster2

```

Warning: make a note of the passphrase - it cannot be displayed again.

Until then, the operational authentication state of the relationship remains as "pending".

```

cluster1::> cluster peer offer show

```

Peer Cluster Name	Authentication	Creation	Expiration	Allowed Server
Peers				

```

-----
cluster2          ok-and-offer    6/7/2017 08:16:10    6/7/2017 09:16:10    -

Modify cluster peer relationship in cluster2 with use-authentication option and use
the auto-generated passphrase.

cluster2::> cluster peer modify -cluster cluster2 -auth-status-admin use-
authentication

Notice: Use a auto-generated passphrase or choose a passphrase of 8 or more
characters.
        To ensure the authenticity of the peering relationship, use a phrase or
sequence
        of characters that would be hard to guess.

Enter the passphrase:
Confirm the passphrase:

```

- [cluster peer create](#)

# cluster peer ping

Initiate intercluster connectivity test

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **cluster peer ping** command displays the status of the network mesh used by the peering relationship. The command checks the network connection to each remote IP address known by the cluster. This includes all intercluster addresses. It is possible for a known address to be not present during the ping. These addresses are not checked, but the absence is temporary.

The most useful parameters for diagnosing problems are **-count** and **-packet-size**. Use the **-count** and **-packet-size** parameters to diagnose problems similarly to how you use them with the standard ping utility.

To display network connection status within a cluster, use the [network ping](#) command.

## Parameters

{ [-fields <fieldname>, ...]

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[`-instance`] }**

If you specify the `-instance` parameter, the command displays detailed information about all fields.

**[`-originating-node` {<nodename>|local}] - Node that Initiates Ping**

Use this parameter to send the ping from the node you specify.

**[`-destination-cluster` <Cluster name>] - Cluster to Ping**

Use this parameter to specify the peer cluster you wish to ping.

**[`-destination-node` <Peer Node Name>] - Node to Ping in Destination Cluster**

Use this parameter to specify a specific node in the destination cluster to ping.

**[`-ip-address` <IP Address>] - Active IP Address**

Use this parameter to specify the active IP address you wish to ping.

**[`-count` <integer>] - Ping Count**

Use this parameter to specify the number of requests to be sent to the destination.

**[`-status` {unknown\_node|internal\_error|unreachable|session\_reachable|interface\_reachable}] - Status of Ping Operation**

Use this parameter to display only ping results that have the status you specify.

**[`-timeout` <integer>] - Ping Timeout in Seconds**

Use this parameter to specify a timeout value in seconds for the ping operation.

**[`-packet-size` <integer>] - Size of Packet**

Use this parameter to specify the number of data bytes to be sent in the ping packet.

**[`-ttl` <integer>] - Time to Live/ Number of Hops**

Use this parameter to specify the maximum number of network hops a packet may make before it is considered a failure.

**[`-response-time` <double>] - Response Time (ms)**

Use this parameter to display only nodes that have the response time (in milliseconds) that you specify. This parameter is most useful when specified with a range of values, such as `>500`

## Examples

This example shows a ping of cluster1 and cluster2 from cluster2. All nodes are reachable.

```
cluster2::> cluster peer ping
Node: node1          Destination Cluster: cluster2
Destination Node IP Address      Count  TTL  RTT(ms)  Status
-----
node1                10.98.228.230      1  255    0.209  interface_reachable
node2                10.98.228.234      1  255    0.42   interface_reachable
```

```

Node: node2                               Destination Cluster: cluster2
Destination Node IP Address              Count  TTL  RTT(ms) Status
-----
node1          10.98.228.230          1  255   0.358 interface_reachable
node2          10.98.228.234          1  255   0.17  interface_reachable
Node: node1                               Destination Cluster: cluster1
Destination Node IP Address              Count  TTL  RTT(ms) Status
-----
node3          10.98.229.22           1  255   0.336 interface_reachable
node4          10.98.229.29           1  255   0.354 interface_reachable
Node: node2                               Destination Cluster: cluster1
Destination Node IP Address              Count  TTL  RTT(ms) Status
-----
node3          10.98.229.22           1  255   0.354 interface_reachable
node4          10.98.229.29           1  255   0.336 interface_reachable
6 entries were displayed.

# cluster peer show

Display peer cluster information

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **cluster peer show** command displays information about the peering relationships between the current cluster and other clusters. Cluster peering enables independent clusters to coordinate and exchange data.

## Parameters

{ [-fields <fieldname>, ...]

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

| [-instance ] }

If you specify the **-instance** parameter, the command displays detailed information about all fields.

[-cluster <text>] - Peer Cluster Name

Selects the peered clusters that match this parameter value.

**[-cluster-uuid <UUID>] - Cluster UUID**

Selects the peered clusters that match this parameter value.

**[-peer-addr <Remote InetAddress>, ...] - Remote Intercluster Addresses**

Selects the peered clusters that match this parameter value (remote-host name or IP address).

**[-availability <availability>] - Availability of the Remote Cluster**

Selects the peered clusters that match this parameter value. This parameter can have four different values:

- Available - The peer cluster availability status will be **Available** only if all the nodes in the local cluster are able to contact all the nodes in the remote cluster.
- Partial - The peer cluster availability status will be **Partial** only if some nodes in the local cluster are not able to contact some or all nodes in the peer cluster.
- Unavailable - The peer cluster availability status will be **Unavailable** only if all the nodes in the local cluster are not able to contact any node in the peer cluster.
- Pending - The peer cluster availability status will be **Pending** while the system is creating in-memory health data.
- Unidentified - The peer cluster availability status will be Unidentified if the cluster peer offer is created for an anonymous cluster and is unused. When the offer is used, then the availability will get changed to any of the above mentioned status.

Note: If one or more nodes in the local cluster are offline or unreachable, then those nodes are not used to determine the availability status for the remote nodes.

**[-rcluster <text>] - Remote Cluster Name**

Selects the peered clusters that match this parameter value.

**[-ip-addr <Remote InetAddress>, ...] - Active IP Addresses**

Selects the peered clusters that match this parameter value.

**[-serialnumber <Cluster Serial Number>] - Cluster Serial Number**

Selects the peered clusters that match this parameter value.

**[-remote-cluster-nodes <text>, ...] - Remote Cluster Nodes**

Selects the peered clusters that match this parameter value.

**[-remote-cluster-health {true|false}] - Remote Cluster Health**

Selects the peered clusters that match this parameter value.

- true - This means that there is cluster quorum in the peer cluster.
- false - This means that there is no cluster quorum in the peer cluster.

**[-unreachable-local-nodes <text>, ...] - Unreachable Local Nodes**

Selects the peered clusters that match this parameter value.

**[-timeout <integer>] - Operation Timeout (seconds)**

Selects the peered clusters that match this parameter value.

**[-address-family {ipv4|ipv6}] - Address Family of Relationship**

Selects the peered clusters that have a relationship established using this protocol.

**[-auth-status-admin {no-authentication|revoked|use-authentication}] - Authentication Status Administrative**

Selects the peered clusters that match this parameter value, which must be chosen from the following values.

- no-authentication - The cluster peer relationship uses no authentication.
- use-authentication - The cluster peer relationship is authenticated.
- revoked - The cluster peer relationship is revoked until agreement can be reached.

**[-auth-status-operational {ok|absent|pending|expired|revoked|declined|refused|ok-and-offer|absent-but-offer|revoked-but-offer|key-mismatch|intent-mismatch|incapable}] - Authentication Status Operational**

Selects the peered clusters that match this parameter value, which must be one of the following values.

- ok - The clusters both use authentication and they have agreed on an authentication key.
- absent - The clusters agree not to use authentication.
- pending - This cluster has made an outstanding offer to authenticate with the other cluster, but agreement has not yet been reached.
- expired - This cluster's offer to authenticate with the other cluster expired before agreement was reached.
- revoked - This cluster has revoked any prior authentication agreement.
- declined - The other cluster has revoked the authentication agreement and is declining to communicate with this cluster.
- refused - The other cluster actively refuses the communication attempts, perhaps because its part of the peering relationship has been deleted.
- ok-and-offer - The clusters agree on an authentication key and are using it. In addition, this cluster has made an outstanding offer to re-authenticate with the other cluster.
- absent-but-offer - The clusters currently agree that neither side requires authentication of the other, but this cluster has made an outstanding offer to authenticate.
- revoked-but-offer - This cluster has revoked any authentication agreement, but it has made an outstanding offer to authenticate.
- intent-mismatch - The two clusters disagree on whether authentication is required.
- key-mismatch - The two clusters both believe that they are authenticated, but one of the shared secrets has become corrupted.
- incapable - The other cluster is no longer running a version of Data ONTAP that supports authenticated cluster peering.

**[-rpc-connect-timeout <integer>] - Timeout for RPC Connect**

Selects the peered clusters that match this parameter value.

**[-update-ping-timeout <integer>] - Timeout for Update Pings**

Selects the peered clusters that match this parameter value.

**[-last-updated <MM/DD/YYYY HH:MM:SS>] - Last Update Time**

Selects the peered clusters that match this parameter value.

**[-ipSpace <IPspace>] - IPspace for the Relationship**

Selects the peered clusters whose relationships are to cross the named local IPspace. The default value is the IPspace name "Default". In relationships created before ONTAP 8.3.1, the initial value is "-" and is not updated to "Default" until an action is taken on a cluster peer relationship, such as creating, modifying, or deleting a relationship.

**[-encryption-protocol-proposed {none|tls-psk}] - Proposed Setting for Encryption of Inter-Cluster Communication**

Selects the peered clusters that match the value of this parameter, that is, whether they are proposing to encrypt their cross-cluster communication or not.

**[-encryption-protocol {none|tls-psk}] - Encryption Protocol For Inter-Cluster Communication**

Selects the peered clusters that match the value of this parameter, that is, whether they are encrypting their cross-cluster communication or not.

**[-psk-algorithm {akep2|jpake}] - Algorithm By Which the PSK Was Derived**

Selects the peered clusters that match the value of this parameter, that is, which of the following algorithms was used to derive the Pre-Shared Key between the clusters.

- akep2 - The key was obtained through the AKEP2-and-PBKDF2 algorithm.
- jpake - The key was obtained through the J-PAKE algorithm.

## Examples

This example shows the output of the cluster peer show command when all nodes in the local cluster are able to contact all nodes in the remote peer cluster. Additionally, the peer relationship is authenticated and operating correctly.

```
cluster1::> cluster peer show
Peer Cluster Name      Cluster Serial Number  Availability  Authentication
-----
cluster2              1-80-123456           Available    ok
```

Detailed information for this scenario is shown below.

```
cluster1::> cluster peer show -instance
Peer Cluster Name: cluster2
```

```

Remote Intercluster Addresses: cluster2-d2, 10.98.234.246
Availability of the Remote Cluster: Available
Remote Cluster Name: cluster2
Active IP Addresses: 10.98.234.246, 10.98.234.243
Cluster Serial Number: 1-80-123456
Remote Cluster Nodes: cluster2-01, cluster2-02
Remote Cluster Health: true
Unreachable Local Nodes: -
Address Family of Relationship: ipv4
Authentication Status Administrative: use-authentication
Authentication Status Operational: ok
Last Update Time: 02/05 21:05:41
IPspace for the Relationship: Default
Encryption for Inter-Cluster Communication: none

```

This example shows the output of the cluster peer show command when some nodes in the local cluster are not able to contact some or all of the nodes in the remote peer cluster.

```

cluster1::> cluster peer show
Peer Cluster Name      Cluster Serial Number Availability  Authentication
-----
cluster2               1-80-123456      Available   ok

```

Detailed information for this scenario is shown below.

```

cluster1::> cluster peer show -instance
Peer Cluster Name: cluster2
Remote Intercluster Addresses: cluster2-d2, 10.98.234.246
Availability of the Remote Cluster: Partial
Remote Cluster Name: cluster2
Active IP Addresses: 10.98.234.246, 10.98.234.243
Cluster Serial Number: 1-80-123456
Remote Cluster Nodes: cluster2-01, cluster2-02
Remote Cluster Health: false
Unreachable Local Nodes: -
Address Family of Relationship: ipv4
Authentication Status Administrative: use-authentication
Authentication Status Operational: ok
Last Update Time: 02/05 21:05:41
IPspace for the Relationship: Default
Encryption for Inter-Cluster Communication: none

```

This example shows the output of the cluster peer show command when some nodes in the local cluster cannot be contacted from the node where the command is executed, but all the other nodes including node on which command is executed are able to contact all nodes in the remote peer cluster.

```
cluster1::> cluster peer show
Peer Cluster Name      Cluster Serial Number Availability  Authentication
-----
cluster2               1-80-123456      Available   ok
```

Detailed information for this scenario is shown below.

```
cluster1::> cluster peer show -instance
Peer Cluster Name: cluster2
Remote Intercluster Addresses: cluster2-d2, 10.98.234.246
Availability of the Remote Cluster: Available
Remote Cluster Name: cluster2
Active IP Addresses: 10.98.234.246, 10.98.234.243
Cluster Serial Number: 1-80-123456
Remote Cluster Nodes: cluster2-01, cluster2-02
Remote Cluster Health: true
Unreachable Local Nodes: cluster1-01
Address Family of Relationship: ipv4
Authentication Status Administrative: use-authentication
Authentication Status Operational: ok
Last Update Time: 02/05 21:05:41
IPspace for the Relationship: Default
Encryption for Inter-Cluster Communication: none
```

This example shows the output of the cluster peer show command when some nodes in the local cluster cannot be contacted from the node where the command is executed, and the node on which command is executed is also not able to contact the remote peer cluster.

```
cluster1::> cluster peer show
Peer Cluster Name      Cluster Serial Number Availability  Authentication
-----
cluster2               1-80-123456      Unavailable ok
```

Detailed information for this scenario is shown below.

```
cluster1::> cluster peer show -instance
Peer Cluster Name: cluster2
Remote Intercluster Addresses: cluster2-d2, 10.98.234.246
Availability of the Remote Cluster: Unavailable
Remote Cluster Name: cluster2
Active IP Addresses: 10.98.234.246, 10.98.234.243
Cluster Serial Number: 1-80-123456
Remote Cluster Nodes: cluster2-01, cluster2-02
Remote Cluster Health: -
Unreachable Local Nodes: cluster1-01
Address Family of Relationship: ipv4
```

```

Authentication Status Administrative: use-authentication
Authentication Status Operational: ok
Last Update Time: 02/05 21:05:41
IPspace for the Relationship: Default
Encryption for Inter-Cluster Communication: none

```

This example shows the output of the `cluster peer show` command when all the nodes in the local cluster are not able to contact any nodes in the remote peer cluster.

```

cluster1::> cluster peer show
Peer Cluster Name      Cluster Serial Number Availability  Authentication
-----
cluster2               1-80-123456      Unavailable  ok

```

Detailed information for this scenario is shown below.

```

cluster1::> cluster peer show -instance
Peer Cluster Name: cluster2
Remote Intercluster Addresses: cluster2-d2, 10.98.234.246
Availability of the Remote Cluster: Unavailable
Remote Cluster Name: cluster2
Active IP Addresses: 10.98.234.246, 10.98.234.243
Cluster Serial Number: 1-80-123456
Remote Cluster Nodes: cluster2-01, cluster2-02
Remote Cluster Health: -
Unreachable Local Nodes: -
Address Family of Relationship: ipv4
Authentication Status Administrative: use-authentication
Authentication Status Operational: ok
Last Update Time: 02/05 21:05:41
IPspace for the Relationship: Default
Encryption for Inter-Cluster Communication: none

```

This example shows the output of the `cluster peer show` command while the system is creating in-memory health data.

```

cluster1::> cluster peer show
Peer Cluster Name      Cluster Serial Number Availability  Authentication
-----
cluster2               1-80-123456      Pending     ok

```

Detailed information for this scenario is shown below.

```

cluster1::> cluster peer show -instance
Peer Cluster Name: cluster2
Remote Intercluster Addresses: cluster2-d2, 10.98.234.246

```

```

Availability of the Remote Cluster: Pending
  Remote Cluster Name: cluster2
  Active IP Addresses: 10.98.234.246, 10.98.234.243
  Cluster Serial Number: 1-80-123456
  Remote Cluster Nodes: -
  Remote Cluster Health: -
  Unreachable Local Nodes: -
  Address Family of Relationship: ipv4
Authentication Status Administrative: use-authentication
  Authentication Status Operational: ok
  Last Update Time: 02/05 21:05:41
  IPspace for the Relationship: Default
Encryption for Inter-Cluster Communication: none

```

This example shows the output of the **cluster peer show** command for the offer created for an anonymous cluster:

```

cluster1::> cluster peer show
Peer Cluster Name      Cluster Serial Number  Availability  Authentication
-----
Clus_4gHR              -                    Unidentified  pending

```

Detailed information for this scenario is shown below.

```

cluster1::> cluster peer show -instance
Peer Cluster Name: Clus_4gHR
  Remote Intercluster Addresses: -
  Availability of the Remote Cluster: Unidentified
  Remote Cluster Name: Clus_4gHR
  Active IP Addresses: 10.98.234.246, 10.98.234.243
  Cluster Serial Number: -
  Remote Cluster Nodes: -
  Remote Cluster Health: -
  Unreachable Local Nodes: -
  Address Family of Relationship: ipv4
Authentication Status Administrative: use-authentication
  Authentication Status Operational: ok
  Last Update Time: 02/05 21:05:41
  IPspace for the Relationship: Default
Encryption for Inter-Cluster Communication: none

```

## cluster peer connection show

Show current peering connections for a cluster

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `cluster peer connection show` command displays information about the current TCP connections and how they are supporting the set of peering relationships.

## Parameters

`{[-fields <fieldname>,...]}`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

`[-instance ]}`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-cluster-name <text>] - Remote Cluster`

Selects the connections associated with the named peered cluster.

`[-node {<nodename>|local}] - Node`

Selects the connections hosted by the given node.

`[-connection-type {mgmt-client|mgmt-server|data}] - Cluster Peering Connection Type`

Selects the connections of the named type. This parameter can have one of three different values:

- `Mgmt-client` - Management-plane client connections, created so that this node may make management-plane requests of other nodes.
- `Mgmt-server` - Management-plane server connections, over which this node services requests made by other nodes' `mgmt-client` connections.
- `Data` - Connections made between data-planes of different nodes.

`[-index <integer>] - Index of Connection`

Selects the connections with the given index value.

`[-cluster-uuid <UUID>] - Cluster UUID`

Selects the connections to the cluster with the given cluster UUID.

`[-auth-status-admin {no-authentication|revoked|use-authentication}] - Authentication Status Administrative`

Selects connections to the peered clusters whose intended authentication matches this parameter value.

`[-auth-status-operational {ok|absent|pending|expired|revoked|declined|refused|ok-and-offer|absent-but-offer|revoked-but-offer|key-mismatch|intent-mismatch|incapable}] - Authentication Status Operational`

**Authentication Status Operational**

Selects connections to the peered clusters whose authentication state matches this parameter value.

**[-authenticated {true|false}] - Authenticated**

Selects connections that have been authenticated, or not, according to this parameter value.

**[-port <integer>] - Network Port**

Selects the connections whose port matches this parameter value.

**[-idle <[<integer>h][<integer>m][<integer>s]>] - Idle Time**

Selects the connections whose idle times match this parameter value.

**[-address <IP Address>] - Remote Network Address**

Selects the connections that have this parameter value as the remote network address.

**[-psk-algorithm {akep2|jpake}] - PSK Algorithm**

Selects the connections for clusters whose PSKs were generated by the named algorithm. This parameter can have one of two different values:

- akep2 - The original algorithm, PBKDF2 followed by AKEP2.
- jpake - Newer algorithm: J-PAKE.

## Examples

This example shows the output of the cluster peer connection show command.

```
cluster1::> cluster peer connection show
Cluster Node           Connection Type  Auth  Encrypt Idle  Remote Address
-----
cluster2
  node1
                                data true  true   6s   10.10.10.100
                                data true  true   7s   10.10.10.100
                                data true  true  20s   10.10.10.100
                                data true  true  11s   10.10.10.100
                                data true  true   7s   10.10.10.100
                                data true  true   7s   10.10.10.100
                                data true  true  11s   10.10.10.200
                                data true  true  11s   10.10.10.200
                                data true  true  48s   10.10.10.200
                                data true  true  48s   10.10.10.200
                                data true  true  37s   10.10.10.200
                                data true  true  37s   10.10.10.200

12 entries were displayed.
```

## cluster peer health show

Check peer cluster health

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **cluster peer health show** command displays information about the health of the nodes in peer clusters from the perspective of the nodes in the local cluster. The command obtains health information by performing connectivity and status probes of each peer cluster's nodes from each node in the local cluster.

To enable quick access to remote cluster health information, remote cluster health status is periodically checked and cached. These cached results enable users and system features to quickly assess the availability of remote resources. By default, this command accesses cached results. Use the **-bypass-cache true** option to force a current, non-cached check of remote cluster health.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[ -originating-node {<nodename>|local} ] - Local Node**

Selects the node that matches this parameter value.

**[ -destination-cluster <Cluster name> ] - Peer Cluster**

Selects the cluster that matches this parameter value.

**[ -destination-node <Peer Node Name> ] - Peer Node**

Selects the node that matches this parameter value.

**[ -destination-cluster-uuid <UUID> ] - Peer UUID**

Selects the cluster that matches this parameter value.

**[ -data-ping {unknown\_node|internal\_error|unreachable|session\_reachable|interface\_reachable} ] - Status of Data Ping Operation**

Selects the nodes that match this parameter value.

**[ -icmp-ping {unknown\_node|internal\_error|unreachable|session\_reachable|interface\_reachable} ] - Status of ICMP Ping Operation**

Selects the nodes that match this parameter value.

**[ -node-health {true|false} ] - RDB Health of the Node**

Selects the nodes that match this parameter value (**true** means healthy).

**[-cluster-health {true|false}] - Cluster Health**

Selects the nodes that match this parameter value (**true** means healthy).

**[-availability {true|false}] - Communication Indicator**

Selects the nodes that match this parameter value (**true** means communicating).

**[-bypass-cache {true|false}] - Bypass Cache and Determine Health**

Bypasses cached results to determine current cluster health (**true** means bypass the cache).  
Cached results may not be current, but they are displayed more quickly.

**[-last-updated <MM/DD/YYYY HH:MM:SS>] - Last Update Time**

Selects the nodes that match this parameter value.

## Examples

The following example shows typical output for this command in a cluster of two nodes that has a peer cluster of two nodes.

```
cluster1::> cluster peer health show
Node      Cluster-Name      Node-Name
          Ping-Status      RDB-Health Cluster-Health Availability
-----
node1
          cluster2      node3
          Data: interface_reachable
          ICMP: -      true      true      true
          node4
          Data: interface_reachable
          ICMP: -      true      true      true
node2
          cluster2      node3
          Data: interface_reachable
          ICMP: -      true      true      true
          node4
          Data: interface_reachable
          ICMP: -      true      true      true
4 entries were displayed.
```

The following example shows detailed health information for node3 in cluster2 from the perspective of node1 in cluster1.

```
cluster1::> cluster peer health show -originating-node node1 -destination-cluster
cluster2 -destination-node node3 -instance
Local Node: node1
          Peer Cluster: cluster2
          Peer Node: node3
          Peer UUID: 5e4befb2-1f36-11d0-98c9-123476563412
```

```
Status of Data Ping Operation: interface_reachable
Status of ICMP Ping Operation: -
    RDB health of the node: true
    Cluster Health: true
Communication Indicator: true
    Last Update Time: 02/06 18:58:38
```

## cluster peer offer cancel

Cancel the outstanding offer to authenticate with a peer cluster

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **cluster peer offer cancel** command cancels an outstanding offer to authenticate with a potentially peered cluster. After the command completes, the given cluster can no longer establish authentication using the given authentication offer.

### Parameters

**-cluster <text>** - Peer Cluster Name

Use this parameter to specify which offer should be cancelled, by specifying the name of the cluster to which the offer is extended.

### Examples

The following example cancels the authentication offer to cluster2.

```
cluster1::> cluster peer offer cancel -cluster cluster2
```

## cluster peer offer modify

Modify an outstanding offer to authenticate with a peer cluster

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **cluster peer offer modify** command modifies the outstanding offer to authenticate with a potentially peered cluster. Every authentication offer has an expiration time, after which the offer will no longer be honored. This command is used to change that expiration time. To cancel the offer outright, use the [cluster peer offer cancel](#) command instead.

## Parameters

### **-cluster <text> - Peer Cluster Name**

Use this parameter to specify the offer to be modified by indicating the name of the cluster to which it has been extended.

### **[-offer-expiration {MM/DD/YYYY HH:MM:SS | {1..7}days | {1..168}hours | PnDTnHnMnS | PnW}] - Authentication Offer Expiration Time**

Use this parameter to specify the new expiration time for the offer.

### **[-initial-allowed-vserver-peers <Vserver Name>, ...] - Vservers Initially Allowed for Peering**

Use this optional parameter to specify the list of Vservers for which reciprocal Vserver peering with peer cluster should be enabled.

## Examples

This example modifies the expiration time for the authentication offer to push it out by an hour.

```
cluster1::> cluster peer offer show
Peer Cluster Name      Authentication Creation      Expiration
-----
cluster2               absent_but_offer
                        7/23/2013 14:45:47 7/23/2013 15:45:47

cluster1::> cluster peer offer modify -cluster cluster2 -offer-expiration "7/23/2013
16:45:47"

cluster1::> cluster peer offer show
Peer Cluster Name      Authentication Creation      Expiration
-----
cluster2               absent_but_offer
                        7/23/2013 14:45:47 7/23/2013 16:45:47
```

## cluster peer offer show

Display outstanding offers to authenticate with a peer cluster

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **cluster peer offer show** command displays information about authentication offers still pending with potential peer clusters. By default, the command displays information about all unexpired offers made by the local cluster.

To display detailed information about a specific offer, run the command with the **-cluster** parameter.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ [-instance ] ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-cluster <text>] - Peer Cluster Name**

Selects the offer that matches this parameter value.

**[-auth-status-operational {ok|absent|pending|expired|revoked|declined|refused|ok-and-offer|absent-but-offer|revoked-but-offer|key-mismatch|intent-mismatch|incapable}] - Authentication Status Operational**

Selects the offers that match this parameter value.

**[-offer-creation <MM/DD/YYYY HH:MM:SS>] - Authentication Offer Creation Time**

Selects the offers that match this parameter value.

**[-offer-expiration {MM/DD/YYYY HH:MM:SS | {1..7}days | {1..168}hours | PnDTnHnMnS | PnW}] - Authentication Offer Expiration Time**

Selects the offers that match this parameter value.

**[-initial-allowed-vserver-peers <Vserver Name>, ...] - Vservers Initially Allowed for Peering**

Selects the offers that match this parameter value.

**[-offer-creator <text>] - Authentication Offer Creator**

Selects the offers that match this parameter value.

**[-encryption-protocol-proposed {none|tls-psk}] - Encryption Protocol to Be Used For the Relationship**

Selects the offers that match this parameter value.

## Examples

The following example displays information about the outstanding authentication offers:

```
cluster1::> cluster peer offer show
```

Peer Cluster Name	Authentication	Creation	Expiration	Allowed Vserver
Peers				
-----				
cluster2	absent_but_offer	7/11/2013 22:22:52	7/11/2013 23:22:52	vs1,vs2

## cluster peer policy modify

Modify the policy configuration for the cluster peering service

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **cluster peer policy modify** command modifies the prevailing policy settings. One setting governs whether unauthenticated cluster peer relationships can exist. The other setting specifies a minimum length for passphrases.

### Parameters

**[-is-unauthenticated-access-permitted {true|false}] - Is Unauthenticated Cluster Peer Access Permitted**

Use this parameter to specify whether unauthenticated peering relationships are allowed to exist. Setting the parameter value to **true** allows such relationships to exist. Setting the value to **false** prevents both the creation of unauthenticated peering relationships as well as the modification of existing peering relationships to be unauthenticated. Setting the value to **false** is not possible if the cluster currently is in any unauthenticated relationships.

**[-passphrase-minlength <integer>] - Passphrase Length Minimum**

Use this parameter to specify a minimum length for passphrases as given to the [cluster peer create](#) or [cluster peer modify](#) commands in the future. The default value for this parameter is 8.

**[-is-unencrypted-access-permitted {true|false}] - Is Unencrypted Cluster Peer Access Permitted**

Use this parameter to specify whether peering relationships that do not use encryption are allowed to exist. Setting the parameter value to **true** allows such relationships to exist. Setting the value to **false** prevents the creation of unauthenticated peering relationships and the modification of existing peering relationships to be unauthenticated, as well as preventing unencrypted peering relationships from being created and the modification of existing peering relationships to be unencrypted. Setting the value to **false** is not possible if the cluster currently is in any unauthenticated or unencrypted relationships.

## Examples

This example modifies the peering policy to disallow unauthenticated intercluster communications.

```
cluster1::> cluster peer policy show
Is Unauthenticated Cluster Peer Communication Permitted: true
                Minimum Length for a Passphrase: 8

cluster1::> cluster peer policy modify -is-unauthenticated-access-permitted false

cluster1::> cluster peer policy show
Is Unauthenticated Cluster Peer Communication Permitted: false
                Minimum Length for a Passphrase: 8
```

## Related Links

- [cluster peer create](#)
- [cluster peer modify](#)

## cluster peer policy show

Display the policy configuration for the cluster peering service

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **cluster peer policy show** command displays the prevailing cluster peer authentication policy. There are two policies at present: one to control whether any cluster peer relationships can be unauthenticated, and one to control the minimum length for a passphrase. If the policy is set to preclude unauthenticated peering relationships, then unauthenticated relationships cannot be created inadvertently. Passphrases of less than the minimum length may not be used. By default, this minimum length is set to 8, so passphrases must be 8 characters long or longer.

## Examples

This example shows the cluster peer policy when unauthenticated relationships may not be created inadvertently.

```
cluster1::> cluster peer policy show
Is Unauthenticated Cluster Peer Communication Permitted: false
                Minimum Length for a Passphrase: 9
Is Unencrypted Cluster Peer Communication Permitted: true
```

# cluster quorum-service options modify

Modify the settings for cluster quorum-service

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `cluster quorum-service options modify` command modifies the values of cluster quorum services options.

## Parameters

### `[-ignore-quorum-warning-confirmations {true|false}] - Whether or Not Warnings Are Enabled`

Specifies whether cluster quorum warnings and confirmations should be ignored when cluster operations could negatively impact cluster quorum:

- Halting a node ([system node halt](#) )
- Rebooting a node ([system node reboot](#) )
- Issuing a planned takeover ([storage failover takeover](#) )

The default setting is false.

## Examples

The following example shows the usage of this command:

```
cluster1::> set advanced
```

```
Warning: These advanced commands are potentially dangerous; use them only when  
directed to do so by Fujitsu personnel.  
Do you want to continue? {y|n}: y
```

```
cluster1::*> cluster quorum-service options modify -ignore-quorum-warning  
-confirmations true
```

## Related Links

# cluster quorum-service options show

Display the settings for cluster quorum-service

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `cluster quorum-service options show` command displays the values of cluster quorum services options.

## Examples

The following example demonstrates showing the state of ignore-quorum-warning-confirmations when it is false and true.

```
cluster1::*> set advanced
```

```
Warning: These advanced commands are potentially dangerous; use them only when
         directed to do so by Fujitsu personnel.
         Do you want to continue? {y|n}: y
```

```
cluster1::*> cluster quorum-service options show
Ignore Quorum Warning Confirmations
-----
false
```

# cluster ring show

Display cluster node member's replication rings

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `cluster ring show` command displays a cluster's ring-replication status. Support personnel might ask you to run this command to assist with troubleshooting.

## Parameters

```
{ [-fields <fieldname>, ...]
```

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[ -node {<nodename>|local} ] - Node**

Selects the rings that match this parameter value.

**[ -unitname {mgmt|vldb|vifmgr|bcomd|crs|availd} ] - Unit Name**

Selects the rings that match this parameter value. Possible values are:

- **mgmt** - The management application
- **vldb** - The volume location database
- **vifmgr** - The virtual-interface manager
- **bcomd** - The SAN management daemon
- **crs** - The configuration replication service

**[ -online {master|secondary|offline} ] - Status**

Selects the rings that match this parameter value.

**[ -epoch <integer> ] - Epoch**

Selects the rings that match this parameter value.

**[ -master <nodename> ] - Master Node**

Selects the rings that match this parameter value.

**[ -local <nodename> ] - Local Node**

Selects the rings that match this parameter value.

**[ -db-epoch <integer> ] - DB Epoch**

Selects the rings that match this parameter value.

**[ -db-trnxs <integer> ] - DB Transaction**

Selects the rings that match this parameter value.

**[ -num-online <integer> ] - Number Online**

Selects the rings that match this parameter value.

**[ -rdb-uuid <UUID> ] - RDB UUID**

Selects the rings that match this parameter value.

## Examples

The following example displays information about all replication rings in a two-node cluster:

```
cluster1::*> cluster ring show
Node      UnitName Epoch   DB Epoch DB Trnxs Master   Online
```

cluster statistics show

```

-----
node0    mgmt    1      1      1068    node0    master

node1    crs    1      1       88     node0    secondary
10 entries were displayed.

```

## cluster statistics show

Display cluster-wide statistics

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **cluster statistics show** command displays the following information. Each item lists the current value and; if applicable, the change (delta) from the previous reported value.

- CPU busy percentage
- Average of CPU busy percentage (advanced privilege level only)
- Total number of NFS and CIFS operations
- Number of NFS operations
- Number of CIFS operations
- Number of cache operations (advanced privilege level only)
- Total amount of network data received (advanced privilege level only)
- Total amount of network data sent (advanced privilege level only)
- Number of packets received (advanced privilege level only)
- Number of packets sent (advanced privilege level only)
- Busy percentage for the data network
- Amount of data received on the data network
- Amount of data sent on the data network
- Busy percentage for the cluster network
- Amount of data received on the cluster network
- Amount of data sent on the cluster network

- Amount of data read from disk
- Amount of data written to disk

At the diagnostic privilege level, the command displays the following information:

- Average of CPU busy percentage
- CPU busy percentage
- Total number of operations
- Number of NFS operations
- Number of CIFS operations
- Number of 7M Fcache operations
- Number of SpinFS operations
- Total amount of network traffic received
- Total amount of network traffic sent
- Percentage of data-network utilization
- Amount of data-network traffic received
- Amount of data-network traffic sent
- Percentage of cluster-network utilization
- Amount of cluster-network traffic received
- Amount of cluster-network traffic sent
- Amount of data read from disk
- Amount of data written to disk
- Number of packets received
- Number of packets sent

## Examples

The following example displays cluster statistics:

```
cluster1::> cluster statistics show
  Counter      Value      Delta
-----
CPU Busy:      84%        +27
Operations:
  Total:       951471448  7210/s:11s
  NFS:        12957951479  13759/s:11s
  CIFS:       342195460   230/s:11s
Data Network:
  Busy:        0%          -
  Received:   1.98TB    3.18MB/s:11s
  Sent:      6.20TB    903KB/s:11s
```

```
Cluster Network:
  Busy:          0%          -
  Received:      6.33TB    1.34MB/s:11s
  Sent:         6.24TB    3.54MB/s:11s
Storage Disk:
  Read:         207TB    82.7MB/s:11s
  Write:        53.3TB   53.5MB/s:11s
```

## cluster time-service ntp key create

Create an NTP symmetric authentication key

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The `cluster time-service ntp key create` command creates a cryptographic key that can be used to verify that Network Time Protocol (NTP) packets are coming from a configured NTP server.

To use the created key it must be assigned to the required NTP server configuration using the [cluster time-service ntp server create](#) or [cluster time-service ntp server modify](#) commands.

The id, key-type and value must all be configured identically on both the ONTAP cluster and the external NTP time server for the cluster to be able to synchronize time to that server.

### Parameters

**-id <integer> - NTP Symmetric Authentication Key ID**

Uniquely identifies this key in the cluster. Must be an integer between 1 and 65535.

**-type <sha1> - NTP Symmetric Authentication Key Type**

The cryptographic algorithm that this key is used with. Only SHA1 is currently supported.

**-value <text> - NTP Symmetric Authentication Key Value**

A 40 character hexadecimal digit string that represents a cryptographic key that is shared with the NTP server.

### Examples

The following example creates a new SHA-1 NTP symmetric authentication key.

```
cluster1::> cluster time-service ntp key create 1 sha1
2e874852e7d41cda65b23915aa5544838b366c51
```

## Related Links

- [cluster time-service ntp server create](#)
- [cluster time-service ntp server modify](#)

# cluster time-service ntp key delete

Delete an NTP symmetric authentication key

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Delete an NTP symmetric authentication key.

It is not possible to delete a key that is referenced in an existing NTP server configuration. Remove all references to this key using the [cluster time-service ntp server modify](#) or [cluster time-service ntp server delete](#) commands before attempting to delete the key using this command.

## Parameters

**-id <integer>** - NTP Symmetric Authentication Key ID

Unique identifier of this key in the cluster.

## Examples

The following example deletes the NTP key with ID 1.

```
cluster1::> cluster time-service ntp key delete 1
```

## Related Links

- [cluster time-service ntp server modify](#)
- [cluster time-service ntp server delete](#)

# cluster time-service ntp key modify

Modify an NTP symmetric authentication key

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `cluster time-service ntp key modify` command modifies a Network Time Protocol (NTP) symmetric authentication key.

## Parameters

**-id <integer>** - NTP Symmetric Authentication Key ID

Unique identifier of this key in the cluster.

**[-type <sha1>]** - NTP Symmetric Authentication Key Type

The cryptographic algorithm that this key is used with. Only SHA1 is currently supported.

**[-value <text>]** - NTP Symmetric Authentication Key Value

A 40 character hexadecimal digit string that represents a cryptographic key that is shared with the NTP server.

## Examples

The following example modifies the NTP key with ID 1 to have a new value.

```
cluster1::> cluster time-service ntp key modify 1 -value
2e874852e7d41cda65b23915aa5544838b366c51
```

# cluster time-service ntp key show

Display NTP symmetric authentication keys

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `cluster time-service ntp key show` command displays the configured Network Time Protocol (NTP) symmetric authentication keys.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

**[ [-instance ] ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-id <integer>] - NTP Symmetric Authentication Key ID**

If this parameter is specified, the command displays the keys that match the specified key ID.

**[-type <sha1>] - NTP Symmetric Authentication Key Type**

If this parameter is specified, the command displays the keys that match the specified key type.

**[-value <text>] - NTP Symmetric Authentication Key Value**

If this parameter is specified, the command displays the keys that match the specified value.

## Examples

The following example displays information about the NTP authentication keys in the cluster:

```
cluster1::> cluster time-service ntp key show
ID      Type      Value
-----
2       sha1      5a01120580b5a6ade6ebcd5bad7673fdd6db0113
10      sha1      1f48d2e6f02f17e3f8fa8798cc77af101df29642
2 entries were displayed.
```

# cluster time-service ntp security modify

Modify NTP security settings

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `cluster time-service ntp security modify` command allows setting of security parameters related to the Network Time Protocol (NTP) subsystem.

## Parameters

**[-is-query-enabled {true|false}] - Is Querying of NTP Server Enabled?**

Setting this parameter to **true** allows querying of the NTP subsystem from systems external to the cluster. For example, querying a node using the standard "ntpq" command can be enabled by this command. The default setting is **false** to protect against possible security vulnerabilities. If querying of the NTP subsystem is disabled, the `cluster time-service ntp status show` command can be used to obtain similar information. Although querying of the NTP subsystem from external hosts can be disabled with this command, executing a local query to the localhost address is always enabled.

## Examples

The following example enables the querying of the NTP subsystem from clients external to the cluster:

```
cluster-1::> cluster time-service ntp security modify -is-query-enabled true
```

## Related Links

- [cluster time-service ntp status show](#)

# cluster time-service ntp security show

Display NTP security settings

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `cluster time-service ntp security show` command displays the configuration of security features related to the Network Time Protocol (NTP) subsystem.

## Examples

The following example displays the NTP security configuration of the cluster:

```
cluster1::> cluster time-service ntp security show
External queries enabled?: true
```

# cluster time-service ntp server create

Add a NTP Server

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `cluster time-service ntp server create` command associates the cluster with an external network time server for time correction and adjustment by using the Network Time Protocol (NTP).

The command resolves the time server host name to an IP address and performs several validation checks. If an error is detected during validation, it is reported.

The validation checks performed by this command include the following:

- The NTP replies to an NTP query with the specified protocol version.
- The NTP reply indicates that the external time server is synchronized to another time server.
- The distance and dispersion of the NTP reply from the "root" or source clock are within the required limits.

## Parameters

### **-server <text> - NTP Server Host Name, IPv4 or IPv6 Address**

This parameter specifies the host name or IP address of the external NTP server that is to be associated with the cluster for time correction and adjustment.

### **[-version {3|4|auto}] - NTP Version for Server (default: auto)**

Use this parameter to optionally specify the NTP protocol version that should be used for communicating with the external NTP server. If the external NTP server does not support the specified protocol version, time exchange cannot take place.

The supported values for this parameter include the following:

- **3** - Use NTP protocol version 3, which is based on Internet Standard request for comments (RFC) #1305.
- **4** - Use NTP protocol version 4, which is based on Internet Standard RFC #5905.
- **auto** - Have Data ONTAP select the NTP protocol version.

The default setting is **auto**.

### **[-is-preferred {true|false}] - Is Preferred NTP Server (default: false)**

Use this parameter to optionally specify whether the external NTP server is the primary time source for correcting and adjusting the cluster time. The responses from this source are used unless its time is outside the accepted selection range.

The default setting is **false**.

You use this parameter when a high quality radio (or GPS) based time server is being used with a set of non-radio based backup time servers.

### **[-key-id <integer>] - NTP Symmetric Authentication Key ID**

Use this parameter to optionally enable NTP symmetric authentication key for communication with the specified time server. The ID must refer to a key created by the [cluster time-service ntp key create](#) command and must be a key with the same ID and value as one configured on the specified time server.

## Examples

The following example associates the cluster with an NTP server named ntp1.example.com.

```
cluster1::> cluster time-service ntp server create -server ntp1.example.com
```

## Related Links

- [cluster time-service ntp key create](#)

# cluster time-service ntp server delete

Delete a NTP Server

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **cluster time-service ntp server delete** command removes the association between the cluster and an external network time server that uses the Network Time Protocol (NTP).

## Parameters

**-server <text>** - NTP Server Host Name, IPv4 or IPv6 Address

This specifies the host name or IP address of an existing external NTP server that the cluster will disassociate from.

## Examples

The following example disassociates an NTP server named ntp2.example.com from the cluster:

```
cluster1::> cluster time-service ntp server delete -server ntp2.example.com
```

# cluster time-service ntp server modify

Modify NTP Server Options

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **cluster time-service ntp server modify** command modifies the configuration of an existing external network time server that uses the Network Time Protocol (NTP) for time correction and adjustment.

## Parameters

### **-server <text> - NTP Server Host Name, IPv4 or IPv6 Address**

This parameter specifies the host name or IP address of an existing external NTP server that is to be modified.

### **[-version {3|4|auto}] - NTP Version for Server (default: auto)**

Use this parameter to optionally specify the NTP protocol version that should be used for communicating with the external NTP server. If the external NTP server does not support the specified protocol version, time exchange cannot take place.

The supported values for this parameter include the following:

- **3** - Use NTP protocol version 3, which is based on Internet Standard request for comments (RFC) #1305.
- **4** - Use NTP protocol version 4, which is based on Internet Standard RFC #5905.
- **auto** - Have Data ONTAP select the NTP protocol version.

The default setting is **auto**.

### **[-is-preferred {true|false}] - Is Preferred NTP Server (default: false)**

Use this parameter to optionally specify whether the external NTP server is the primary time source for correcting and adjusting the cluster time. The responses from this source are used unless its time is outside the accepted selection range

The default setting is **false**.

You use this parameter when a high quality radio (or GPS) based time server is being used with a set of non-radio based backup time servers.

This parameter is available only at the advanced privilege level and higher.

### **[-is-authentication-enabled {true|false}] - Is NTP Symmetric Key Authentication Enabled**

Use this parameter to optionally disable NTP symmetric key authentication for communication with the specified time server. Using this parameter and selecting **false** disables the NTP symmetric key authentication and clears the **key-id** parameter for the specified server. This parameter is not required to enable NTP symmetric key authentication, but if specified as **true** the NTP symmetric authentication key must also be specified using the **key-id** parameter.

### **[-key-id <integer>] - NTP Symmetric Authentication Key ID**

Use this parameter to optionally enable NTP symmetric authentication key for communication with the specified time server. The ID must refer to a key created by the [cluster time-service ntp key create](#) command and must be a key with the same ID and value as one configured on the specified time server.

## Examples

The following example modifies the NTP version of an NTP server named ntp1.example.com. The NTP version is changed to 4.

```
cluster1::> cluster time-service ntp server modify -server ntp1.example.com -version 4
```

## Related Links

- [cluster time-service ntp key create](#)

# cluster time-service ntp server reset

Reset NTP server list to a default selection

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `cluster time-service ntp server reset` command replaces the current configuration with one of the selected configurations.

If none or more than one time service configuration is selected, the command will fail.

## Parameters

**[-use-public {true|false}] - Reset Server List to Public Identified Defaults (default: false)**

When set to true, this specifies that the public NTP server list used by Data ONTAP should replace the current configuration.

The default setting is **false**.

## Examples

The following example replaces the current time service configuration with the default public NTP server list that is used by Data ONTAP.

```
cluster1::> cluster time-service ntp server reset -use-public true
```

# cluster time-service ntp server show

Display a list of NTP Servers

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `cluster time-service ntp server show` command displays the association between the cluster and external network time servers that use the Network Time Protocol (NTP).

## Parameters

`{ [-fields <fieldname>, ... ] }`

If you specify the `-fields <fieldname>, ...` parameter, the command only displays the fields that you specify. For example: `-fields server, version`.

`[ [-instance ] ] }`

If this parameter is specified, the command displays all the available field information.

`[-server <text>] - NTP Server Host Name, IPv4 or IPv6 Address`

If this parameter is specified, the command displays the external NTP servers that match the specified server name or IP address.

`[-version {3|4|auto}] - NTP Version for Server (default: auto)`

If this parameter is specified, the command displays the external NTP servers that use the specified NTP version.

`[-is-preferred {true|false}] - Is Preferred NTP Server (default: false)`

If this parameter is specified, the command displays the external NTP server or servers that match the specified preferred server status.

`[-is-public {true|false}] - Is Public NTP Server Default`

If this parameter is specified, the command displays the information for the external NTP servers that are either on the NTP server list defined by Data ONTAP (`true` ``) or not on the list (`false` ``).

`[-is-authentication-enabled {true|false}] - Is NTP Symmetric Key Authentication Enabled`

If this parameter is specified, the command displays the external NTP server or servers that require NTP symmetric key authentication for communication.

`[-key-id <integer>] - NTP Symmetric Authentication Key ID`

If this parameter is specified, the command displays the external NTP server or servers that match the specified symmetric authentication key ID.

## Examples

The following example displays information about all external NTP time servers that are associated with the cluster:

```
cluster1::> cluster time-service ntp server show
                Is
                Authentication
Server          Version  Enabled  Key ID
-----
ntp1.example.com auto    false   -
ntp2.example.com auto    true    10
```

## cluster time-service ntp status show

Display status of the node's NTP client

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

The `cluster time-service ntp status show` command displays the status of the associations between the cluster and external network time servers that use the Network Time Protocol (NTP).

### Parameters

`{ [-fields <fieldname>, ... ] }`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

`[ -instance ] }`

If this parameter is specified, the command displays detailed information about all entries.

`[ -node {<nodename>|local} ] - Node`

If this parameter is specified, the command displays information related to associations on the specified node.

`[ -server <text> ] - NTP Server Host Name, IPv4 or IPv6 Address`

If this parameter is specified, the command displays information about the associations related to the specified NTP server. The server should be specified as it is configured in the [cluster time-service ntp server show](#) command.

`[ -server-address <IP Address> ] - Server IP Address`

If this parameter is specified, the command displays information about the associations related to the NTP server with the specified IP address.

`[ -is-peer-reachable {true|false} ] - Is Peer Reachable and Responding to Polls?`

If this parameter is specified as **true**, the command displays information about associations with the NTP servers that have been successfully polled.

**[-is-peer-selected {true|false}] - Is Peer Selected as Clock Source?**

If this parameter is specified as **true**, the command displays information about associations with the NTP servers that have been selected as the current clock source.

**[-selection-state <State of NTP Peer Selection>] - State of Server Selection**

If this parameter is specified, the command displays information about associations with the specified selection state.

**[-selection-state-text <text>] - Description of Server Selection State**

If this parameter is specified, the command displays information about associations with the specified selection state description.

**[-poll-interval <integer>] - Poll Interval (secs)**

If this parameter is specified, the command displays information about associations that have the specified polling interval.

**[-time-last-poll <integer>] - Time from Last Poll (secs)**

If this parameter is specified, the command displays information about associations that are polled at the specified time.

**[-offset <double hundredths>] - Offset from Server Time (ms)**

If this parameter is specified, the command displays information about associations with the specified offset from the NTP server.

**[-delay <double hundredths>] - Delay Time to Server (ms)**

If this parameter is specified, the command displays information about associations with the specified travelling time to the NTP server.

**[-jitter <double hundredths>] - Maximum Offset Error (ms)**

If this parameter is specified, the command displays information about associations with the specified offset error from the NTP server.

**[-reachability <Hex String>] - Reachability of Server**

If this parameter is specified, the command displays information about associations with the specified reachability to the NTP server. Reachability is specified as a hexbyte that has a bit to represent the success of each of the last eight polls of the specified server. A set bit represents a successful poll. The least significant bit represents the most recent poll, the next most significant bit the poll before that, and so on.

**[-server-stratum <integer>] - Stratum of Server Clock**

If this parameter is specified, the command displays information about associations with NTP servers with the specified clock stratum.

**[-server-reference <text>] - Reference Clock at Server**

If this parameter is specified, the command displays information about associations with NTP servers using the specified clock as reference.

**[~~-reported-errors~~ <NTP Peer and Packet Errors>,···] - Reported Packet and Peer Errors**

If this parameter is specified, the command displays information about associations with the specified errors.

## Examples

The following example displays the status of the NTP associations of the cluster:

```
cluster-1::*>cluster time-service ntp status show
Node: node-1
Server                Reachable  Selection State                Offset (ms)
-----
ntp1.eng.netapp.com   true      Currently Selected Server      39.122
ntp2.eng.netapp.com   true      Candidate Server                37.786
2 entries were displayed.
```

The following example displays the status of the association with the specified external NTP server:

```
cluster-1::*>cluster time-service ntp status show -instance -server ntp1.example.com
Node: node-1
NTP Server Host Name, IPv4 or IPv6 Address: ntp1.example.com
Server IP Address: 10.56.32.33
Is Peer Reachable and Responding to Polls?: true
Is Peer Selected as Clock Source?: true
State of Server Selection: sys_peer
Description of Server Selection State: Currently Selected Server
Poll Interval (secs): 64
Time from Last Poll (secs): 1
Offset from Server Time (ms): 26.736
Delay Time to Server (ms): 61.772
Maximum Offset Error (ms): 3.064
Reachability of Server: 01
Stratum of Server Clock: 2
Reference Clock at Server: 10.56.68.21
Reported Packet and Peer Errors: -
```

## Related Links

- [cluster time-service ntp server show](#)

## event catalog show

Display event definitions

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **event catalog show** command displays information about events in the catalog. By default, this command displays the following information:

- Message name of the event
- Severity of the event
- SNMP trap type of the event

To display detailed information about a specific event, run the command with the **-message-name** parameter, and specify the name of the event. The detailed view adds the following information:

- Full description of the event
- Action to be taken to address the event
- Event's deprecation status

You can specify additional parameters to limit output to the information that matches those parameters. For example, to display information only about events with an event name that begins with **raid**, enter the command with the `-message-name`raid*` parameter. The parameter value can either be a specific text string or a wildcard pattern.

Alternatively, an event filter can also be specified to limit the output events.

## Parameters

**{ [-fields <fieldname>,...]**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

**[-instance ]}**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-message-name <Message Name>] - Message Name**

Selects the events that match this parameter value.

**[-filter-name <text>] - Filter Name**

Selects the events that match this parameter value. The parameter value indicates an existing filter name that, when applied permits the inclusion of the listed events.

**[-severity {EMERGENCY|ALERT|ERROR|NOTICE|INFORMATIONAL|DEBUG}] - Severity**

Selects the events that match this parameter value.

**[-description <text>] - Description**

Selects the events that match this parameter value.

**[-action <text>] - Corrective Action**

Selects the events that match this parameter value.

**[-snmp-trap-type {Standard|Built-in|Severity-based}] - SNMP Trap Type**

Selects the events that match this parameter value. The parameter value describes the type of SNMP trap associated with the event. The value can be one of the following: **Standard** trap type events are those defined in the RFCs. **Built-in** trap types are those that are Fujitsu Enterprise traps specific to events. The remaining events are considered to have **Severity-based** SNMP trap types.

**[-deprecated {true|false}] - Is Deprecated**

Selects the events that match this parameter value. The parameter value indicates whether the event is deprecated or not.

Deprecated events may be removed in a future release of Data ONTAP.

## Examples

The following example displays the event catalog:

```
cluster1::> event filter show -filter-name filter1
Filter Name Rule      Rule      Message Name      SNMP Trap Type  Severity
      Position Type
-----
filter1
      1      include  zapi.*            *                *
      2      exclude  *                  *                *
```

2 entries were displayed.

```
cluster1::> event catalog show -filter-name filter1
Message                      Severity      SNMP Trap Type
-----
zapi.killed                  NOTICE      Severity-based
zapi.method.notfound         NOTICE      Severity-based

## event config force-sync

Synchronize a node's EMS configuration with the cluster wide EMS configuration

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

The **event config force-sync** command forces a node's EMS configuration to be synchronized with the cluster wide EMS configuration. The configuration is automatically synchronized among all nodes in the cluster, but in rare cases a node may not be updated. This command simplifies the recovery from this issue.

The following example shows where this command is useful: An email destination is configured for all CRITICAL level event occurrences. When the event is generated, all nodes generate an email except one. This command forces that node to refresh a stale configuration.

### Parameters

**[-node {<nodename>|local}] - Node**

The node parameter specifies which controller will be synchronized.

## event config modify

Modify log configuration parameters

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

Use the **event config modify** command to configure event notification and logging for the cluster.

### Parameters

**[-mail-from <mail address>] - Mail From**

Use this parameter to configure the email address from which email notifications will be sent. You can configure the cluster to send email notifications when specific events occur. Use the **event route add-destinations** and **event destination create** commands to configure email destinations for events.

**[-mail-server <text>] - Mail Server (SMTP)**

Use this parameter to configure the name or IP address of the SMTP server used by the cluster when sending email notification of events.

**[-suppression {on|off}] - Event Throttling/Suppression**

Use this parameter to configure whether event suppression algorithms are enabled ("on") or disabled ("off"). The event processing system implements several algorithms to throttle duplicate events.

**[-console {on|off}] - Console Logging**

Use this parameter to configure whether events are displayed on the console port ("on") or not displayed("off").

**[-proxy-url <text>] - HTTP/HTTPS Proxy URL**

If your organization uses a proxy, use this parameter to specify an HTTP or HTTPS proxy for rest-api type EMS notification destinations. The URL must start with an http:// prefix. HTTPS connections to a proxy are not supported. To specify a URL that contains a question mark, press ESC followed by the "?".

**[-proxy-user <text>] - User Name for HTTP/HTTPS Proxy**

If authentication is required, use this parameter to specify the user name for the HTTP or HTTPS proxy server specified by the **-proxy-url** parameter. Use the [event config set-proxy-password](#) command to set the password used for this user name.

**[-is-pubsub-enabled {true|false}] - Is Publish/Subscribe Messaging Enabled?**

Use this parameter to configure whether or not events are published to the Publish/Subscribe messaging broker.

## Examples

The following command sets the "Mail From" address for event notifications to "[admin@example.com](mailto:admin@example.com)" and the "Mail Server" to "mail.example.com":

```
cluster1::> event config modify -mailfrom admin@example.com -mailserver
mail.example.com
```

The following command configures a proxy that requires authentication:

```
cluster1::> event config modify -proxy-url http://proxy.example.com:8080 -proxy-user
-name admin
cluster1::> event config set-proxy-password

Enter the password:
Confirm the password:
```

The following example turns on event suppression and console logging:

```
cluster1::> event config modify -suppression on -console on
```

## Related Links

- [event config set-proxy-password](#)

# event config set-proxy-password

Modify password for proxy server

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Use the **event config set-proxy-password** command to set the password for authenticated access to an HTTP or HTTPS proxy being used for EMS notifications. This password is used with the user name you specify using the [event config modify -proxy-user](#) command to send EMS messages to REST API destinations via the proxy you specify using the [event config modify -proxy-url](#) command. IF you enter the command without parameters, the command prompts you for a password and for a confirmation of that password. Enter the same password at both prompts. The password is not displayed.

## Parameters

## Examples

The following example shows successful execution of this command:

```
cluster1::> event config set-proxy-password
```

```
Enter the password:
```

```
Confirm the password:
```

## Related Links

- [event config modify](#)

# event config show

Display log configuration parameters

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **event config show** command displays information about the configuration of event notification and event logging for the cluster.

"Mail From" is the email address that the event notification system uses as the "From" address for email notifications.

"Mail Server" is the name or IP address of the SMTP server that the event notification system uses to send email notification of events.

"Proxy URL" is the HTTP or HTTPS proxy server URL used by rest-api type EMS notification destinations if your organization uses a proxy.

"Proxy User Name" is the user name for the HTTP or HTTPS proxy server if authentication is required.

"Is Publish/Subscribe Messaging Enabled?" indicates whether or not events are published to the Publish/Subscribe messaging broker.

"Suppression" indicates whether event suppression algorithms are enabled ("on") or disabled ("off"). The event processing system implements several algorithms to throttle events.

The suppression parameter can disable both autosuppression and duplicate suppression, but not timer suppression.

"Console" indicates whether events are displayed on the console port ("on") or not displayed ("off").

## Examples

The following example displays the configuration of event notification for the cluster:

```
cluster1::> event config show
                Mail From:  admin@example.com
                Mail Server: mail.example.com
                Proxy URL:   -
                Proxy User Name: -
                Publish/Subscribe Messaging Enabled: true
```

The following example displays the configuration of event notification with HTTP or HTTPS proxy:

```
cluster1::> event config show
                Mail From:  admin@example.com
                Mail Server: mail.example.com
                Proxy URL:  http://proxy.example.com:3128
                Proxy User Name: admin
                Publish/Subscribe Messaging Enabled: true
```

# event filter copy

Copy an event filter

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **event filter copy** command copies an existing filter to a new filter. The new filter will be created with rules from the source filter. For more information, see the [event filter create](#) command.

## Parameters

### **-filter-name <text> - Filter Name**

Use this mandatory parameter to specify the name of the event filter to copy.

### **-new-filter-name <text> - New Event Filter Name**

Use this mandatory parameter to specify the name of the new event filter to create and copy the rules.

## Examples

The following example copies an existing event filter named `emer-wafl-events` to a new filter named `filter1`:

```
cluster1::> event filter show
Filter Name Rule      Rule      Message Name      SNMP Trap Type  Severity
           Position Type
-----
default-trap-events
           1      include   *                *                EMERGENCY, ALERT
           2      include   *                Standard, Built-in
                                           *
           3      exclude  *                *                *
emer-wafl-events
           1      include   wafl.*           *                EMERGENCY
           2      exclude  *                *                *
important-events
           1      include   *                *                EMERGENCY, ALERT
           2      include   callhome.*       *                ERROR
           3      exclude  *                *                *
no-info-debug-events
           1      include   *                *                EMERGENCY,
ALERT, ERROR, NOTICE
           2      exclude  *                *                *
10 entries were displayed.
```

```

cluster1::> event filter copy -filter-name emer-wafl-events -new-filter-name filter1

cluster1::> event filter show
Filter Name Rule      Rule      Message Name      SNMP Trap Type  Severity
      Position Type
-----
default-trap-events
      1      include  *           *           EMERGENCY, ALERT
      2      include  *           Standard, Built-in
      3      exclude  *           *           *
emer-wafl-events
      1      include  wafl.*      *           EMERGENCY
      2      exclude  *           *           *
filter1
      1      include  wafl.*      *           EMERGENCY
      2      exclude  *           *           *
important-events
      1      include  *           *           EMERGENCY, ALERT
      2      include  callhome.*  *           ERROR
      3      exclude  *           *           *
no-info-debug-events
      1      include  *           *           EMERGENCY,
ALERT, ERROR, NOTICE

Filter Name Rule      Rule      Message Name      SNMP Trap Type  Severity
      Position Type
-----
no-info-debug-events
      2      exclude  *           *           *
12 entries were displayed.

```

- [event filter create](#)

# event filter create

Create a new event filter.

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **event filter create** command creates a new event filter. An event filter is used to select the events of interest and is made up of one or more rules, each of which contains the following three fields:

\*

- name - event (message) name.
- severity - event severity.
- snmp-trap-type - event SNMP trap type.

These fields are evaluated for a match using a logical "AND" operation: name AND severity AND SNMP trap type. Within a field, the specified values are evaluated with an implicit logical "OR" operation. So, if ``-snmp-trap-type` ``_Standard, Built-in_``` is specified, then the event must match ```_Standard_``` OR ```_Built-in_```. The wildcard matches all values for the field.

\* Type - include or exclude. When an event matches an include rule, it will be included into the filter, whereas it will be excluded from the filter if it matches an exclude rule.

Rules are checked in the order they are listed for a filter, until a match is found. There is an implicit rule at the end that matches every event to be excluded. For more information, see the **event filter rule** command.

There are three system-defined event filters provided for your use:

- default-trap-events - This filter matches all ALERT and EMERGENCY events. It also matches all Standard, Built-in SNMP trap type events.
- important-events - This filter matches all ALERT and EMERGENCY events.
- no-info-debug-events - This filter matches all non-INFO and non-DEBUG messages (EMERGENCY, ALERT, ERROR and NOTICE).

The system-defined event filters cannot be modified or deleted.

## Parameters

### **-filter-name <text> - Filter Name**

Use this mandatory parameter to specify the name of the event filter to create. An event filter name is 2 to 64 characters long. Valid characters are the following ASCII characters: A-Z, a-z, 0-9, `"`, and `'`. The name must start and end with: A-Z, a-z, `"`, or 0-9.

## Examples

The following example creates an event filter named filter1:

```
cluster1::> event filter create -filter-name filter1

cluster1::> event filter show
Filter Name Rule      Rule      Message Name      SNMP Trap Type  Severity
          Position Type
```

```

-----
default-trap-events
    1      include  *          *          EMERGENCY, ALERT
    2      include  *          Standard, Built-in
                                   *
    3      exclude *          *          *
filter1
    1      exclude *          *          *
important-events
    1      include  *          *          EMERGENCY, ALERT
    2      include  callhome.* *          ERROR
    3      exclude *          *          *
no-info-debug-events
    1      include  *          *          EMERGENCY,
ALERT, ERROR, NOTICE
    2      exclude *          *          *
9 entries were displayed.
    
```

# event filter delete

Delete existing event filters

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **event filter delete** command deletes an existing event filter, along with all its rules.

The system-defined event filters cannot be deleted.

For more information, see the [event filter create](#) command.

## Parameters

**-filter-name <text> - Filter Name**

Use this mandatory parameter to specify the name of the event filter to delete.

## Examples

The following example deletes an event filter named filter1:

```

cluster1::> event filter show
Filter Name Rule      Rule      Message Name      SNMP Trap Type  Severity
           Position Type
-----
default-trap-events
    
```

```

      1      include * * EMERGENCY, ALERT
      2      include * Standard, Built-in
                    *
filter1      3      exclude * * *
      1      include waf.* * EMERGENCY
      2      exclude * * *
important-events
      1      include * * EMERGENCY, ALERT
      2      include callhome.* * ERROR
      3      exclude * * *
no-info-debug-events
      1      include * * EMERGENCY,
ALERT, ERROR, NOTICE
      2      exclude * * *
10 entries were displayed.

```

```
cluster1::> event filter delete -filter-name filter1
```

```
cluster1::> event filter show
```

Filter Name	Rule Position	Rule Type	Message Name	SNMP Trap Type	Severity
-----					
default-trap-events					
	1	include	*	*	EMERGENCY, ALERT
	2	include	*	Standard, Built-in	*
	3	exclude	*	*	*
important-events					
	1	include	*	*	EMERGENCY, ALERT
	2	include	callhome.*	*	ERROR
	3	exclude	*	*	*
no-info-debug-events					
	1	include	*	*	EMERGENCY,
	2	exclude	*	*	*

8 entries were displayed.

# event filter rename

Rename an event filter

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **event filter rename** command is used to rename an existing event filter.

There are system-defined event filters provided for your use. The system-defined event filters cannot be modified or deleted.

For more information, see the [event filter create](#) comamnd.

## Parameters

### **-filter-name <text> - Filter Name**

Use this mandatory parameter to specify the name of the event filter to rename.

### **-new-filter-name <text> - New Event Filter Name**

Use this mandatory parameter to specify the new name the event filter should be renamed to.

## Examples

The following example renames an existing filter named filter1 as emer-wafl-events:

```
cluster1::> event filter show
Filter Name Rule    Rule    Message Name          SNMP Trap Type  Severity
          Position Type
-----
default-trap-events
          1    include *          *          EMERGENCY, ALERT
          2    include *          Standard, Built-in
          3    exclude *          *          *
filter1
          1    include waf1.*    *          EMERGENCY
          2    exclude *          *          *
important-events
          1    include *          *          EMERGENCY, ALERT
          2    include callhome.* *          ERROR
          3    exclude *          *          *
no-info-debug-events
          1    include *          *          EMERGENCY,
ALERT, ERROR, NOTICE
          2    exclude *          *          *
10 entries were displayed.
cluster1::> event filter rename -filter-name filter1 -new-filter-name emer-wafl-events

cluster1::> event filter show
Filter Name Rule    Rule    Message Name          SNMP Trap Type  Severity
          Position Type
-----
```

```

default-trap-events
  1      include  *          *          EMERGENCY, ALERT
  2      include  *          Standard, Built-in
  3      exclude *          *          *
emer-wafl-events
  1      include  wafl.*    *          EMERGENCY
  2      exclude  *          *          *
important-events
  1      include  *          *          EMERGENCY, ALERT
  2      include  callhome.* *          ERROR
  3      exclude  *          *          *
no-info-debug-events
  1      include  *          *          EMERGENCY,
ALERT, ERROR, NOTICE
  2      exclude  *          *          *
10 entries were displayed.

```

- [event filter create](#)

# event filter show

Display the list of existing event filters.

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **event filter show** command displays all the event filters which are configured. An event filter is used to select the events of interest and is made up of one or more rules, each of which contains the following three fields:

\*

- name - event (message) name.
- severity - event severity.
- snmp-trap-type - event SNMP trap type.

These fields are evaluated for a match using a logical "AND" operation: name AND severity AND SNMP trap type. Within a field, the specified values are evaluated with an implicit logical "OR" operation. So, if ``-snmp-trap-type``_Standard, Built-in_``` is specified, then the event must match ```_Standard_``` OR ```_Built-in_```. The wildcard matches all values for the field.

\* Type - include or exclude. When an event matches an include rule, it will be

included into the filter, whereas it will be excluded from the filter if it matches an exclude rule.

Rules are checked in the order they are listed for a filter, until a match is found. There is an implicit rule at the end that matches every event to be excluded. For more information, see **event filter rule** command.

There are three system-defined event filters provided for your use:

- **default-trap-events** - This filter matches all ALERT and EMERGENCY events. It also matches all Standard, Built-in SNMP trap type events.
- **important-events** - This filter matches all ALERT and EMERGENCY events.
- **no-info-debug-events** - This filter matches all non-INFO and non-DEBUG messages (EMERGENCY, ALERT, ERROR and NOTICE).

The system-defined event filters cannot be modified or deleted.

## Parameters

### { [-fields <fieldname>, ... ] }

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

### [ [-instance ] ] }

If you specify the **-instance** parameter, the command displays detailed information about all fields.

### [-filter-name <text>] - Filter Name

Selects the event filters that match this parameter value.

### [-position <integer>] - Rule Position

Selects the event filters that match this parameter value.

### [-type {include|exclude}] - Rule Type

Selects the event filters that match this parameter value. The rule types are as follows:

- **include** - Events matching this rule are included in the specified filter.
- **exclude** - Events matching this rule are excluded in the specified filter.

### [-message-name <text>] - Message Name

Selects the event filters that match this parameter value.

### [-severity <text>, ...] - Severity

Selects the events that match this parameter value. Severity levels:

- **EMERGENCY** - Disruption.
- **ALERT** - Single point of failure.

- ERROR - Degradation.
- NOTICE - Information.
- INFORMATIONAL - Information.
- DEBUG - Debug information.
- \* - Includes all severities.

### **[-snmp-trap-type <text>,...] - SNMP Trap Type**

Selects the event filters that match this parameter value. The SNMP trap types are as follows:

- Standard - Traps defined in RFCs.
- Built-in - Enterprise traps specific to events.
- Severity-based - Traps specific to events that do not belong to the above two types.
- \* - Includes all SNMP trap types.

## Examples

The following example displays the event filters:

```
cluster1::> event filter show
Filter Name Rule      Rule      Message Name      SNMP Trap Type  Severity
           Position Type
-----
default-trap-events
           1      include  *                *                EMERGENCY, ALERT
           2      include  *                Standard, Built-in
                                           *
           3      exclude *                *                *
important-events
           1      include  *                *                EMERGENCY, ALERT
           2      exclude *                *                *
no-info-debug-events
           1      include  *                *                EMERGENCY,
ALERT, ERROR, NOTICE
           2      exclude *                *                *
7 entries were displayed.
```

The following example displays the event filters queried on the SNMP trap type value "Standard":

```
cluster1::> event filter show -snmp-trap-type Standard
Filter Name Rule      Rule      Message Name      SNMP Trap Type  Severity
           Position Type
-----
default-trap-events
           2      include  *                Standard, Built-in
                                           *
```

The following example displays the event filters with one or more rules that have no condition on the SNMP trap type. Note that the wildcard character has to be specified in double-quotes. Without double-quotes, output would be the same as not querying on the field.

```
cluster1::> event filter show -snmp-trap-type "*"
Filter Name Rule      Rule      Message Name      SNMP Trap Type  Severity
      Position Type
-----
default-trap-events
      1      include   *                *                EMERGENCY, ALERT
      3      exclude  *                *                *
important-events
      1      include   *                *                EMERGENCY, ALERT
      2      exclude  *                *                *
no-info-debug-events
      1      include   *                *                EMERGENCY,
ALERT, ERROR, NOTICE
      2      exclude  *                *                *
6 entries were displayed.
```

## event filter test

Test an event filter

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **event filter test** command is used to test an event filter. When specified with a message name, the command displays whether the message name is included or excluded from the filter. When specified without a message name, the command displays the number of events from the catalog that match the filter. For more information, see the [event filter create](#) command.

### Parameters

**-filter-name <text> - Filter Name**

Use this mandatory parameter to specify the name of the event filter to test.

**[-message-name <Message Name>] - Message Name**

Use this optional parameter to specify the message name of the event to test against the filter.

### Examples

The following example tests an event filter named `err-wafl-no-scan-but-clone`:

```

cluster1::> event filter show
Filter Name Rule      Rule      Message Name      SNMP Trap Type  Severity
      Position Type
-----
default-trap-events
      1      include  *              *              EMERGENCY, ALERT
      2      include  *              Standard, Built-in
      *
      3      exclude  *              *              *
err-wafl-no-scan-but-clone
      1      include  wafl.scan.clone.*  *              *
      2      exclude  wafl.scan.*        *              *
      3      include  wafl.*             *              EMERGENCY,
ALERT, ERROR
      4      exclude  *              *              *
important-events
      1      include  *              *              EMERGENCY, ALERT
      2      include  callhome.*         *              ERROR
      3      exclude  *              *              *
no-info-debug-events
      1      include  *              *              EMERGENCY,
ALERT, ERROR, NOTICE

Filter Name Rule      Rule      Message Name      SNMP Trap Type  Severity
      Position Type
-----
no-info-debug-events
      2      exclude  *              *              *
12 entries were displayed.

cluster1::> event filter test -filter-name err-wafl-no-scan-but-clone
271 events will be included in the given filter.

cluster1::> event filter test -filter-name err-wafl-no-scan-but-clone -message-name
wafl.scan.clone.split.cantLock
The message-name "wafl.scan.clone.split.cantLock" is included in the given filter.

cluster1::> event filter test -filter-name err-wafl-no-scan-but-clone -message-name
wafl.scan.layout.cantWrite
The message-name "wafl.scan.layout.cantWrite" is excluded from the given filter.

```

- [event filter create](#)

# event filter rule add

Add a rule for an event filter

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `event filter rule add` command adds a new rule to an existing event filter. See [event filter create](#) for more information on event filters and how to create a new event filter.

## Parameters

### `-filter-name <text>` - Filter Name

Use this mandatory parameter to specify the name of the event filter to add the rule. Rules cannot be added to system-defined event filters.

### `[-position <integer>]` - Rule Position

Use this optional parameter to specify the position of the rule in the event filter. It should be in the range (1..n-1), where 'n' is the position of the last rule, which is an implicit rule. Rules are checked in the order they are listed for a filter, until a match is found.

### `-type {include|exclude}` - Rule Type

Use this mandatory parameter to specify the type of the rule which determines whether to include or exclude the events that match this rule.

### `[-message-name <text>]` - Message Name

Use this parameter to specify the message name of the event to include or exclude from the filter.

### `[-severity <text>,...]` - Severity

Use this parameter to specify the list of severity values to match against the events. Enter multiple severities separated by a comma. To enter all severities, the wild card (\*) can be used. The wild card cannot be specified with other severities. The default value is \*.

### `[-snmp-trap-type <text>,...]` - SNMP Trap Type

Use this parameter to specify the list of the SNMP trap type values to match against the events. Enter multiple SNMP trap types separated by comma. To enter all SNMP trap types, the wild card (\*) can be used. The wild card cannot be specified with other SNMP trap types. The default value is \*.

## Examples

The following example adds a rule to an existing event filter "emer-and-wafl": All events with severity EMERGENCY and message name starting with "wafl." are included in the filter. **Not specifying the SNMP trap type implies a default value of ""**.

```
cluster1::> event filter rule add -filter-name emer-and-wafl -type include -message
-name wafl.* -severity EMERGENCY
cluster1::> event filter show
```

Filter Name	Rule Position	Rule Type	Rule	Message Name	SNMP Trap Type	Severity
-----						
default-trap-events	1	include	*	*		EMERGENCY, ALERT
	2	include	*	Standard, Built-in		*
	3	exclude	*	*		*
emer-and-wafl	1	include	wافل.*	*		EMERGENCY
	2	exclude	*	*		*
important-events	1	include	*	*		EMERGENCY, ALERT
	2	include	callhome.*	*		ERROR
	3	exclude	*	*		*
no-info-debug-events	1	include	*	*		EMERGENCY, ALERT, ERROR, NOTICE
	2	exclude	*	*		*
10 entries were displayed.						

The following example adds a rule to the event filter "emer-and-wafl" at position 1: All events with severity ALERT and message name starting with "wafl.scan.\*" are included in the filter.

```
cluster1::> event filter rule add -filter-name emer-and-wafl -type include -message -name wafl.scan.* -position 1 -severity ALERT
```

```
cluster1::> event filter show
```

Filter Name	Rule Position	Rule Type	Rule	Message Name	SNMP Trap Type	Severity
-----						
default-trap-events	1	include	*	*		EMERGENCY, ALERT
	2	include	*	Standard, Built-in		*
	3	exclude	*	*		*
emer-and-wafl	1	include	wافل.scan.*	*		ALERT
	2	include	wافل.*	*		EMERGENCY
	3	exclude	*	*		*
important-events	1	include	*	*		EMERGENCY, ALERT
	2	include	callhome.*	*		ERROR
	3	exclude	*	*		*
no-info-debug-events	1	include	*	*		EMERGENCY, ALERT, ERROR, NOTICE
	2	exclude	*	*		*
11 entries were displayed.						

The following example adds a rule to the event filter "emer-and-wafl" to include all "Standard" SNMP trap type events:

```
cluster1::> event filter rule add -filter-name emer-and-wafl -type include -snmp-trap
-type Standard

cluster1::> event filter show
Filter Name Rule      Rule      Message Name      SNMP Trap Type  Severity
  Position Type
-----
default-trap-events
  1      include  *        *                  EMERGENCY, ALERT
  2      include  *        Standard, Built-in
                                     *
  3      exclude  *        *                  *
emer-and-wafl
  1      include  wafl.scan.*      *                  ALERT
  2      include  wafl.*           *                  EMERGENCY
  3      include  *                Standard           *
  4      exclude  *                *                  *
important-events
  1      include  *                *                  EMERGENCY, ALERT
  2      include  callhome.*       *                  ERROR
  3      exclude  *                *                  *
no-info-debug-events
  1      include  *                *                  EMERGENCY, ALERT,
ERROR, NOTICE
  2      exclude  *                *                  *
12 entries were displayed.
```

- [event filter create](#)

# event filter rule delete

Delete a rule for an event filter

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **event filter rule delete** command deletes a rule from an event filter. The position of all the rules following the deleted rule is updated to maintain a contiguous sequence. Use [event filter show](#) command to view the filters and the rules associated with them.

## Parameters

### -filter-name <text> - Filter Name

Use this mandatory parameter to specify the name of the event filter from which you want to delete the rule. Rules cannot be deleted from system-defined filters.

### -position <integer> - Rule Position

Use this mandatory parameter to specify the position of the rule to delete from the filter. It should be in the range (1..n-1), where 'n' is the position of the last rule, which is an implicit rule.

## Examples

The following example deletes a rule at position 2 from an existing event filter "emer-and-wafl":

```
cluster1::> event filter show
Filter Name Rule    Rule    Message Name          SNMP Trap Type  Severity
      Position Type
-----
default-trap-events
  1      include  *      *                      *                EMERGENCY, ALERT
  2      include  *      Standard, Built-in    *                *
  3      exclude  *      *                      *                *
emer-and-wafl
  1      include  wafl.scan.*          *                ALERT
  2      include  wafl.*                *                EMERGENCY
  3      include  *                    Standard          *                *
  4      exclude  *      *                      *                *
important-events
  1      include  *      *                      *                EMERGENCY, ALERT
  2      include  callhome.*          *                ERROR
  3      exclude  *      *                      *                *
no-info-debug-events
  1      include  *      *                      *                EMERGENCY, ALERT,
ERROR, NOTICE
  2      exclude  *      *                      *                *
12 entries were displayed.
cluster1::> event filter rule delete -filter-name emer-and-wafl -position 2
```

```
cluster1::> event filter show
Filter Name Rule    Rule    Message Name          SNMP Trap Type  Severity
      Position Type
-----
default-trap-events
  1      include  *      *                      *                EMERGENCY, ALERT
  2      include  *      Standard, Built-in    *                *
  3      exclude  *      *                      *                *
emer-and-wafl
```

```

1      include  wafl.scan.*      *      ALERT
2      include  *                Standard *
3      exclude *                *      *
important-events
1      include  *                *      EMERGENCY, ALERT
2      include  callhome.*      *      ERROR
3      exclude *                *      *
no-info-debug-events
1      include  *                *      EMERGENCY, ALERT,
ERROR, NOTICE
2      exclude *                *      *
11 entries were displayed.
```

- [event filter show](#)

# event filter rule reorder

Modify the index of a rule for an event filter

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **event filter rule reorder** command moves a rule to a new position in an existing event filter. Use [event filter show](#) command to display all the event filters and the rules associated with them.

## Parameters

### **-filter-name <text> - Filter Name**

Use this mandatory parameter to specify the name of the event filter from which you want to change the position of the rule. Rules from system-defined event filters cannot be modified.

### **-position <integer> - Rule Positon**

Use this mandatory parameter to specify the position of the rule you want to change. It should be in the range (1..n-1), where 'n' is the position of the last rule, which is an implicit rule.

### **-to-position <integer> - New Rule Position**

Use this mandatory parameter to specify the new position to move the rule. It should be in the range (1..n-1), where 'n' is the position of the last rule, which is an implicit rule.

## Examples

The following example changes the position of a rule from 1 to 2 from an existing event filter "emer-

and-wafl":

```
cluster1::> event filter show
Filter Name Rule      Rule      Message Name      SNMP Trap Type  Severity
           Position Type
-----
default-trap-events
           1      include  *              *              EMERGENCY, ALERT
           2      include  *              Standard, Built-in
                                   *
           3      exclude *              *              *
emer-and-wafl
           1      include  wafl.scan.*      *              ALERT
           2      include  *              Standard        *
           3      exclude *              *              *
important-events
           1      include  *              *              EMERGENCY, ALERT
           2      include  callhome.*      *              ERROR
           3      exclude *              *              *
no-info-debug-events
           1      include  *              *              EMERGENCY,
ALERT, ERROR, NOTICE
           2      exclude *              *              *
11 entries were displayed.
```

```
cluster1::> event filter rule reorder -filter-name emer-and-wafl -position 1 -to
-position 2
```

```
cluster1::> event filter show
Filter Name Rule      Rule      Message Name      SNMP Trap Type  Severity
           Position Type
-----
default-trap-events
           1      include  *              *              EMERGENCY, ALERT
           2      include  *              Standard, Built-in
                                   *
           3      exclude *              *              *
emer-and-wafl
           1      include  *              Standard        *
           2      include  wafl.scan.*      *              ALERT
           3      exclude *              *              *
important-events
           1      include  *              *              EMERGENCY, ALERT
           2      include  callhome.*      *              ERROR
           3      exclude *              *              *
no-info-debug-events
           1      include  *              *              EMERGENCY,
ALERT, ERROR, NOTICE
           2      exclude *              *              *
11 entries were displayed.
```

- [event filter show](#)

# event log show

Display latest log events

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **event log show** command displays the contents of the event log, which lists significant occurrences within the cluster. Use the [event catalog show](#) command to display information about events that can occur.

By default, the command displays EMERGENCY, ALERT and ERROR severity level events with the following information, with the most recent events listed first:

- The time at which the event occurred
- The node on which the event occurred
- The severity of the event
- The event's message

To display detailed information about events, use one or more of the optional parameters that affect how the command output is displayed and the amount of detail that is included. For example, to display all detailed event information, use the **-detail** parameter.

To display NOTICE, INFORMATIONAL or DEBUG severity level events, use the **-severity** parameter.

## Parameters

**{ [-fields <fieldname>, ... ]**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ [-detail ]**

Displays additional event information such the sequence number of the event.

**[ [-detailtime ]**

Displays detailed event information in reverse chronological order.

**[ [-instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node**

Displays a list of events for the node you specify. Use this parameter with the **-seqnum** parameter to display detailed information.

**[-seqnum <Sequence Number>] - Sequence#**

Selects the events that match this parameter value. Use with the **-node** parameter to display detailed information.

**[-time <MM/DD/YYYY HH:MM:SS>] - Time**

Selects the events that match this parameter value. Use the format: MM/DD/YYYY HH:MM:SS [+/-HH:MM]. You can specify a time range by using the "." operator between two time statements.

```
show -time "08/13/2010 05:55:00".. "08/13/2010 06:10:00"
```

Comparative time values are relative to "now". For example, to display only events that occurred within the last minute:

```
show -time >1m
```

+

NOTE: The month and date fields of this parameter are not zero-padded. These fields can be single digits: for example, "7/1/2019 05:55:00".

+

**[-severity {EMERGENCY|ALERT|ERROR|NOTICE|INFORMATIONAL|DEBUG}] - Severity**

Selects the events that match this parameter value. Severity levels are as follows:

- EMERGENCY - Disruption.
- ALERT - Single point of failure.
- ERROR - Degradation.
- NOTICE - Information.
- INFORMATIONAL - Information.
- DEBUG - Debug information.

To display all events, including ones with severity levels of NOTICE, INFORMATIONAL and DEBUG, specify severity as follows:

```
show -severity <=DEBUG
```

**[-ems-severity {NODE\_FAULT|SVC\_FAULT|NODE\_ERROR|SVC\_ERROR|WARNING|NOTICE|INFO|DEBUG|VAR}] - EMS Severity**

Selects the events that match this parameter value. Severity levels:

- **NODE\_FAULT** - Data corruption has been detected or the node is unable to provide client service
- **SVC\_FAULT** - A temporary loss of service, typically a transient software fault, has been detected
- **NODE\_ERROR** - A hardware error that is not immediately fatal has been detected
- **SVC\_ERROR** - A software error that is not immediately fatal has been detected
- **WARNING** - A high-priority message that does not indicate a fault
- **NOTICE** - A normal-priority message that does not indicate a fault
- **INFO** - A low-priority message that does not indicate a fault
- **DEBUG** - A debugging message
- **VAR** - A message with variable severity, selected at runtime.

**[-source <text>] - Source**

Selects the events that match this parameter value (typically a software module).

**[-message-name <Message Name>] - Message Name**

Selects the events that match this parameter value (string). Message names are descriptive, so filtering output by message name displays messages of a specific type.

**[-event <text>] - Event**

Selects the events that match this parameter value. The "event" field contains the full text of the event, including any parameters. For example, a wafl.vol.offline event will contain the name of the volume taken offline.

**[-kernel-generation-num <integer>] - Kernel Generation Number**

Selects the events that match this parameter value. Only events that emanate from the kernel have kernel generation numbers.

**[-kernel-sequence-num <integer>] - Kernel Sequence Number**

Selects the events that match this parameter value. Only events that emanate from the kernel have kernel sequence numbers.

**[-action <text>] - Corrective Action**

Selects the events that match this parameter value. The "action" field describes what steps, if any, you must take to remedy the situation.

**[-description <text>] - Description**

Selects the events that match this parameter value. The "description" field describes why the event was encountered and what it means.

**[-filter-name <Filter Name>] - Filter Name**

Selects the events that match this parameter value. Only events that were included by existing filters that match this value are displayed.

## Examples

The following example displays the event log:

```
cluster1::> event log show
Time                Node                Severity            Event
-----
11/9/2015 13:54:19 node1                NOTICE            vifmgr.portup: A link up event was
received on node node1, port e0a.
11/9/2015 13:54:19 node1                NOTICE            vifmgr.portup: A link up event was
received on node node1, port e0d.
11/9/2015 13:54:19 node1                NOTICE            vifmgr.portup: A link up event was
received on node node1, port e0c.
11/9/2015 13:54:19 node1                NOTICE            vifmgr.portup: A link up event was
received on node node1, port e0b.
...
```

This example demonstrates how to use a range with the **-time** parameter to display all events that occurred during an extended time period. It displays all events that occurred between 1:45pm and 1:50pm on November 9, 2010.

```
cluster1::> event log show -time "11/9/2015 13:45:00".."11/9/2015 13:50:0"
```

The **-time** parameter also accepts values that are relative to "now". The following example displays events that occurred more than one hour ago:

```
cluster1::event log> show -time <1h
Time                Node                Severity            Event
-----
11/9/2015 13:02:03 node1                INFORMATIONAL      monitor.globalStatus.ok: The
system's global status is normal.
11/9/2015 13:02:03 node2                INFORMATIONAL      monitor.globalStatus.ok: The
system's global status is normal.
...
```

Severity levels sort in the order opposite to what you might expect. The following example displays all events that have a severity level of ERROR or more severe:

```
cluster1::> event log show -severity <ERROR
```

- [event catalog show](#)

# event notification create

Create an event notification

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `event notification create` command is used to create a new notification of a set of events defined by an event filter to one or more notification destinations.

## Parameters

### `-filter-name <text>` - Filter Name

Use this mandatory parameter to specify the name of the event filter. Events that are included in the event filter are forwarded to the destinations specified in the destinations parameter.

The filter name passed to this command must be an existing filter. For more information, see the [event filter create](#) command.

### `-destinations <text>,...` - List of Event Notification Destinations

Use this mandatory parameter to specify the list of destinations to which the notification should be forwarded. Enter multiple destinations separated by a comma.

The destination passed to this command must be an existing destination. For more information, see the `event destination create` command.

## Examples

The following example creates an event notification for filter name "filter1" to destinations "email\_dest, snmp-traphost and syslog\_dest":

```
cluster1::> event notification destination show
Name          Type      Hide
-----
email_dest    email    false  test@example.com
snmp-traphost snmp      true   10.27.12.1 (from "system snmp traphost")
syslog_dest   syslog   false  10.23.12.1
3 entries were displayed.

cluster1::> event filter show -filter-name filter1
Filter Name Rule      Rule      Message Name      SNMP Trap Type  Severity
          Position Type
-----
filter1
          1      exclude  callhome.bad.ram  *                *
```

```

      2      include  callhome.*      *      ALERT, ERROR
      3      exclude *              *      *

```

3 entries were displayed.

```
cluster1::> event notification create -filter-name filter1 -destinations
email_dest,syslog_dest,snmp-traphost
```

```
cluster1::> event notification show
```

```

ID      Filter Name      Destinations
-----  -
1       filter1              email_dest, syslog_dest, snmp-traphost

```

## Related Links

- [event filter create](#)

# event notification delete

Delete event notifications

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **event notification delete** command deletes an existing event notification.

## Parameters

**-ID <integer> - Event Notification ID**

Use this parameter to specify the ID of the notification to be deleted.

## Examples

The following example shows the deletion of event notification with ID 1:

```

cluster1::> event notification show
ID      Filter Name      Destinations
-----  -
1       filter1              email_dest, syslog_dest, snmp-traphost

cluster1::> event notification delete -ID 1

cluster1::> event notification show
This table is currently empty.

```

# event notification modify

Modify event notifications

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **event notification modify** command is used to modify an existing notification.

## Parameters

**-ID <integer> - Event Notification ID**

Use this mandatory parameter to specify the ID of the notification to be modified.

**[-filter-name <text>] - Event Filter Name**

Use this parameter to specify the filter name to be modified.

**[-destinations <text>, ...] - List of Event Notification Destinations**

Use this parameter to specify the destinations to be modified. Enter multiple destinations separated by a comma.

Provide the complete set of destinations to be modified. Individual destination cannot be added or removed.

## Examples

The following example shows the modification of event notification with ID 1:

```
cluster1::> event notification show
ID      Filter Name      Destinations
-----  -
1       filter1           email_dest, syslog_dest, snmp-traphost

cluster1::> event notification modify -ID 1 -destinations email_dest, syslog_dest

cluster1::> event notification show
ID      Filter Name      Destinations
-----  -
1       filter1           email_dest, syslog_dest
```

## event notification show

Display event notifications

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **event notification show** command is used to display the list of existing event notifications.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-ID <integer>] - Event Notification ID**

Use this parameter to display the detailed information about the notification ID you specify.

**[-filter-name <text>] - Event Filter Name**

Use this parameter to display event notifications that use the filter-name you specify.

**[-destinations <text>, ...] - List of Event Notification Destinations**

Use this parameter to display event notifications that use the destinations you specify.

## Examples

The following example displays the event notification:

```
cluster1::> event notification show
ID      Filter Name      Destinations
-----  -
1       filter1          email_dest, syslog_dest, snmp-traphost
```

## event notification destination create

Create an event notification destination

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **event notification destination create** command creates a new event notification destination of either email or syslog type.

The following system-defined notification destination is configured for your use:

- `snmp-traphost` - This destination reflects the configuration in "system snmp traphost".

## Parameters

### `-name <text>` - Destination Name

Use this mandatory parameter to specify the name of the notification destination that is to be created. An event notification destination name must be 2 to 64 characters long. Valid characters are the following ASCII characters: A-Z, a-z, 0-9, "\_", and "-". The name must start and end with: A-Z, a-z, or 0-9.

### `{-email <mail address>}` - Email Destination

Use this parameter to specify the email address event notifications are sent to. For events to properly generate email notifications, the event system must also be configured with an address and mail server from which the mail will be sent. See [event config modify](#) command for more information.

### `[-syslog <text>]` - Syslog Destination

Use this parameter to specify the syslog server host name or IP address syslog messages are sent to.

### `[-syslog-port <integer>]` - Syslog Port

Use this parameter to specify the syslog server port value syslog messages are sent to. The default port used depends on the `syslog-transport` value. If the `syslog-transport` is set to `tcp-encrypted`, the `syslog-port` has the default value 6514. If the `syslog-transport` is set to `tcp-unencrypted`, the `syslog-port` has the default value 601. Otherwise, the default `syslog-port` is set to 514.

### `[-syslog-transport {udp-unencrypted|tcp-unencrypted|tcp-encrypted}]` - Syslog Transport

Use this parameter to specify the transport protocol that is used to send the syslog messages.

The `syslog-transport` can be one of the following values:

- `udp-unencrypted` - User Datagram Protocol with no security
- `tcp-unencrypted` - Transmission Control Protocol with no security
- `tcp-encrypted` - Transmission Control Protocol with Transport Layer Security (TLS)

The default protocol is `udp-unencrypted`. If `tcp-encrypted` transport is specified, then ONTAP verifies the identity of the destination host by validating its certificate. If the Online Certificate Status Protocol (OCSP) is enabled for Event Management System (EMS), then ONTAP uses that protocol to determine the certificate's revocation status. Use the (privilege: advanced) [security config ocsf show -application ems](#) command to determine if the OCSP-based certificate revocation status check is enabled for EMS.

### `[-syslog-message-format {legacy-netapp|rfc-5424}]` - Syslog Message Format

Use this parameter to specify the message format to be used for EMS syslog messages.

The **syslog-message-format** can be one of the following values:

- **legacy-netapp** - Variation of RFC-3164 Syslog format (format: <PRIVAL>TIMESTAMP [HOSTNAME:Event-name:Event-severity]: MSG)
- **rfc-5424** - Syslog format as per RFC-5424 (format: <PRIVAL>VERSION TIMESTAMP HOSTNAME Event-source - Event-name - MSG)

Refer to the respective RFCs for detailed information on the syslog message formats. + The default message format is **legacy-netapp** .

#### **[-syslog-timestamp-format-override {no-override|rfc-3164|iso-8601-utc|iso-8601-local-time}] - Syslog Timestamp Format Override**

Use this parameter to override the default timestamp format (based on the **syslog-message-format** parameter) used for EMS syslog messages.

The **syslog-timestamp-format-override** can be one of the following values:

- **no-override** - Timestamp format based on the **syslog-message-format** parameter (**rfc-3164** if message format is **legacy-netapp** , **iso-8601-local-time** if message format is **rfc-5424** )
- **rfc-3164** - Timestamp format as per RFC-3164 (format: Mmm dd hh:mm:ss)
- **iso-8601-utc** - Timestamp format as per ISO-8601 in UTC (format: YYYY-MM-DDThh:mm:ssZ)
- **iso-8601-local-time** - Timestamp format as per ISO-8601 in local time (format: YYYY-MM-DDThh:mm:ss+/-hh:mm)

The default value is **no-override** . When this parameter is modified, its value persists even when **syslog-message-format** is updated. +

#### **[-syslog-hostname-format-override {no-override|fqdn|hostname-only}] - Syslog Hostname Format Override**

Use this parameter to override the default hostname format (based on the **syslog-message-format** parameter) used for EMS syslog messages.

The **syslog-hostname-format-override** can be one of the following values:

- **no-override** - Hostname format based on the **syslog-message-format** parameter (**fqdn** if message format is **rfc-5424** , **hostname-only** if message format is **legacy-netapp** )
- **fqdn** - Fully Qualified Domain Name (e.g., myhost.example.com)
- **hostname-only** - Hostname only, without the domain name (e.g., myhost)

The default value is **no-override** . When this parameter is modified, its value persists even when **syslog-message-format** is updated. +

#### **| -rest-api-url <text> - REST API Server URL**

Use this parameter to specify the REST API server URL to which event notifications are sent. Enter the full URL, which must start either with an `http://` or `https://` prefix. To specify a URL that contains a question mark, press ESC followed by the `"?"`. + If a `https://` URL is specified, then ONTAP verifies the identity of the destination host by validating its certificate. If the Online Certificate Status Protocol (OCSP) is enabled for Event Management System (EMS), then ONTAP

uses that protocol to determine the certificate's revocation status. Use the (privilege: advanced) `security config oosp show -application ems` command to determine if the OCSP-based certificate revocation status check is enabled for EMS.

### **[-certificate-authority <text>] - Client Certificate Issuing CA**

Use this parameter to specify the name of the certificate authority (CA) that signed the client certificate that will be sent in case mutual authentication with the REST API server is required. + There can be multiple client certificates installed for the admin vserver in the cluster, and this parameter, along with the **certificate-serial** parameter, uniquely identifies which one. + Use the `security certificate show` command to see the list of certificates installed in the cluster.

### **[-certificate-serial <text>] - Client Certificate Serial Number }**

Use this parameter to specify the serial number of the client certificate that will be sent in case mutual authentication with the REST API server is required.

## Examples

The following example shows the creation of a new event notification destination of type email called "StorageAdminEmail":

```
cluster1::> event notification destination create -name StorageAdminEmail -email
StorageAdmin@example.com

cluster1::> event notification destination show
```

Name	Type	Destination
StorageAdminEmail	email	StorageAdmin@example.com
snmp-traphost	snmp	10.30.40.10 (from "system snmp traphost")

2 entries were displayed.

The following example shows the creation of a new event notification destination of type rest-api called "RestApi":

```
cluster1::> event notification destination create -name RestApi -rest-api-url
https://rest.example.com/rest
-certificate-authority cluster1-root-ca -certificate-serial 052213E60B7088

cluster1::> event notification destination show -name RestApi -instance
```

Destination Name: RestApi  
 Type of Destination: rest-api  
 Destination Values: https://rest.example.com/rest  
 Client Certificate Issuing CA: cluster1-root-ca  
 Client Certificate Serial Number: 052213E60B7088

# event notification destination delete

Delete existing event destinations

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **event notification destination delete** command deletes an event notification destination.

The following system-defined notification destination is configured for your use:

- **snmp-traphost** - This destination reflects the configuration in "system snmp traphost". To remove snmp-traphost addresses, use the **system snmp traphost** command.

## Parameters

**-name <text> - Destination Name**

Use this mandatory parameter to specify the name of an event destination to be removed.

## Examples

The following shows the examples of deleting event notification destinations:

```
cluster1::> event notification destination show
Name           Type           Destination
-----
StorageAdminEmail
                email         StorageAdmin@example.com
StorageAdminSyslog
                syslog        example.com
snmp-traphost  snmp           10.30.40.10 (from "system snmp traphost")
3 entries were displayed.
cluster1::> event notification destination delete -name StorageAdminEmail

cluster1::> event notification destination show

Name           Type           Destination
-----
StorageAdminSyslog
```

```

                syslog      example.com
snmp-traphost  snmp        10.30.40.10 (from "system snmp traphost")
2 entries were displayed.
cluster1::> event notification destination delete -name Storage*
cluster1::> event notification destination show
Name           Type           Destination
-----
snmp-traphost  snmp          10.30.40.10 (from "system snmp traphost")
1 entries were displayed.

```

## event notification destination modify

Modify an event notification destination

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **event notification destination modify** command modifies an event notification destination. More detailed information about parameters can be found in the man page for the [event notification destination create](#) command.

The following system-defined notification destination is configured for your use:

- snmp-traphost - This destination reflects the configuration in "system snmp traphost". To modify traphost addresses, use the **system snmp traphost** command.

### Parameters

#### **-name <text> - Destination Name**

Use this mandatory parameter to specify the name of an event notification destination to be modified. The name of the destination must already exist.

#### **{ [-email <mail address>] - Email Destination**

Use this parameter to specify a new value of email address to replace the current address in the event notification destination. The parameter is specified only when the event notification destination type is already "email". It is not allowed to specify the parameter for a destination that already has another type of destination address.

#### **[ [-syslog <text>] - Syslog Destination**

Use this parameter to specify a new syslog server host name or IP address to replace the current address of the event notification destination. The parameter is specified only when the event notification destination type is already "syslog". It is not allowed to specify the parameter for a destination that already has another type of destination address.

**[-syslog-port <integer>] - Syslog Port**

Use this parameter to specify a new syslog server port value to replace the current port value of the event notification destination. The parameter is specified only when the event notification destination type is already "syslog". It is not allowed to specify the parameter for a destination that already has another type of destination address.

**[-syslog-transport {udp-unencrypted|tcp-unencrypted|tcp-encrypted}] - Syslog Transport**

Use this parameter to specify a new syslog transport to replace the current transport of the event notification destination. The parameter is specified only when the event notification destination type is already "syslog". It is not allowed to specify the parameter for a destination that already has another type of destination address.

**[-syslog-message-format {legacy-netapp|rfc-5424}] - Syslog Message Format**

Use this parameter to specify a new syslog message format to replace the current message format of the event notification destination.

**[-syslog-timestamp-format-override {no-override|rfc-3164|iso-8601-utc|iso-8601-local-time}] - Syslog Timestamp Format Override**

Use this parameter to override the default syslog timestamp format (based on the **syslog-message-format** parameter) of the event notification destination.

**[-syslog-hostname-format-override {no-override|fqdn|hostname-only}] - Syslog Hostname Format Override**

Use this parameter to override the default syslog hostname format (based on the **syslog-message-format** parameter) of the event notification destination.

**[[-rest-api-url <text>] - REST API Server URL**

Use this parameter to specify a new REST API server URL to replace the current address of the event notification destination. Enter the full URL, which must start either with an `http://` or `https://` prefix. + To specify a URL that contains a question mark, press ESC followed by the "?". + If a `https://` URL is specified, then ONTAP verifies the identity of the destination host by validating its certificate. If the Online Certificate Status Protocol (OCSP) is enabled for Event Management System (EMS), then ONTAP uses that protocol to determine the certificate's revocation status. Use the **security config oscp show -application ems** command to determine if the OCSP-based certificate revocation status check is enabled for EMS. The parameter is specified only when the event notification destination type is already "rest-api". It is not allowed to specify the parameter for a destination that already has another type of destination address.

**[-certificate-authority <text>] - Client Certificate Issuing CA**

Use this parameter to specify a new value of the certificate authority (CA) to replace the current value in the event notification destination. There can be multiple client certificates installed for the admin vserver in the cluster, and this parameter, along with the **certificate-serial** parameter, uniquely identifies which one. + Use the **security certificate show** command to see the list of certificates installed in the cluster.

**[-certificate-serial <text>] - Client Certificate Serial Number }**

Use this parameter to specify a new serial number of the client certificate to replace the current

value in the event notification destination.

## Examples

The following example shows the modification of event notification destinations:

```
cluster1::> event notification destination show
```

Name	Type	Destination
StorageAdminEmail	email	Storage@example.com
StorageAdminSyslog	syslog	example.com
snmp-traphost	snmp	10.30.40.10 (from "system snmp traphost")

3 entries were displayed.

```
cluster1::> event notification destination modify -name StorageAdminEmail -email
StorageAdmin@example.com
```

```
cluster1::> event notification destination show
```

Name	Type	Destination
StorageAdminEmail	email	StorageAdmin@example.com
StorageAdminSyslog	syslog	example.com
snmp-traphost	snmp	10.30.40.10 (from "system snmp traphost")

3 entries were displayed.

The following example shows how to clear the client certificate configuration when mutual authentication with the REST API server is no longer required:

```
cluster1::> event notification destination show -name RestApi -instance
Destination Name: RestApi
Type of Destination: rest-api
Destination Values: https://rest.example.com/rest
Client Certificate Issuing CA: cluster1-root-ca
Client Certificate Serial Number: 052213E60B7088
```

```
cluster-1::> event notification destination modify -name RestApi -certificate
-authority - -certificate-serial -
```

```
cluster-1::> event notification destination show -name RestApi -instance
Destination Name: RestApi
Type of Destination: rest-api
Destination Values: https://rest.example.com/rest
```

```
Client Certificate Issuing CA: -
Client Certificate Serial Number: -
```

# event notification destination prepare-for-revert

Deletes or updates unsupported syslog destinations (transport=TCP or transport=UDP with non-default configurations: port, message-format, timestamp-format-override, hostname-format-override)

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **event notification destination prepare-for-revert** can be used to remove or update syslog notification destinations that are not supported when the cluster reverts to the previous release. Supported syslog destinations are ones with **udp-unencryptedsyslog-transport** using **syslog-port`514** and **legacy\_netapp`syslog-message-format** with **syslog-timestamp-format-override** and **syslog-hostname-format-override** both set to **no-override**. Syslog destinations with any other configurations are not supported.

## Parameters

**{ -delete-unsupported-syslog-destinations {true|false} - Clear unsupported syslog destinations**

Use this parameter to delete syslog destinations that are not supported in the previous release.

**{ -update-unsupported-syslog-destinations {true|false} - Update unsupported syslog destinations to supported }**

Use this parameter to update syslog destinations that are not supported in the previous release with supported configurations.

## Examples

The following shows examples of "event notification destination prepare-for-revert":

```
cluster1::*> event notification destination show
Name           Type           Destination
-----
```

```

snmp-traphost snmp - (from "system snmp traphost")
tst01 syslog test.com (port: 6514, transport: tcp-encrypted)
tst02 syslog test.com (port: 601, transport: tcp-unencrypted)
tst03 syslog test.com (port: 1234, transport: udp-unencrypted)
tst04 syslog test.com (port: 514, transport: udp-unencrypted)
5 entries were displayed.

```

```

cluster1::*> event notification destination prepare-for-revert -delete-unsupported
-syslog-destinations true

```

```

cluster1::*> event notification destination show

```

```

Name          Type          Destination
-----
snmp-traphost snmp          - (from "system snmp traphost")
tst04         syslog        test.com (port: 514, transport: udp-unencrypted)
2 entries were displayed.

```

## event notification destination show

Display event notification destinations

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **event notification destination show** command displays event notification destinations. More detailed information about parameters can be found in the man page for the [event notification destination create](#) command.

Note: In the case of a rest-api destination type or syslog destination type (with tcp-encrypted transport), Online Certificate Status Protocol (OCSP) information is not included. OCSP information is available in the [security config ocsp show -app ems](#) command.

### Parameters

{ [-fields <fieldname>, ... ] }

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

{ [-instance ] }

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-name <text>] - Destination Name**

Use this optional parameter to display information of an event notification destination that has the specified name.

**[-type {snmp|email|syslog|rest-api}] - Type of Destination**

Use this optional parameter to display information of event notification destinations that have the specified destination type.

**[-destination <text>,...] - Destination**

Use this optional parameter to display information of event notification destinations that have the specified destination address. Enter multiple addresses separated by a comma.

**[-server-ca-present {true|false}] - Server CA Certificates Present?**

Use this optional parameter to display information of event notification destinations that have the specified server-ca-present value. This field indicates whether there are certificates of the server-ca type exist in the system. If not, event messages will not be sent to a rest-api type destination having an HTTPS URL.

**[-certificate-authority <text>] - Client Certificate Issuing CA**

Use this optional parameter to display information of event notification destinations that have the specified certificate authority name.

**[-certificate-serial <text>] - Client Certificate Serial Number**

Use this optional parameter to display information of event notification destinations that have the specified certificate serial number.

**[-certificate-valid {true|false}] - Client Certificate Valid?**

Use this optional parameter to display information of event notification destinations that have the specified certificate-valid value. This field indicates whether the client certificate specified by the certificate-authority and certificate-serial fields is valid. If not, and if the REST API server requires client authentication, event messages are not sent to the server.

**[-syslog-port <integer>] - Syslog Port**

Use this optional parameter to display information about an event notification destination that has the specified syslog port.

**[-syslog-transport {udp-unencrypted|tcp-unencrypted|tcp-encrypted}] - Syslog Transport**

Use this optional parameter to display information about an event notification destination that has the specified syslog transport.

**[-syslog-message-format {legacy-netapp|rfc-5424}] - Syslog Message Format**

Use this optional parameter to display information about an event notification destination that has the specified syslog message format.

**[-syslog-timestamp-format-override {no-override|rfc-3164|iso-8601-utc|iso-8601-local-time}] - Syslog Timestamp Format Override**

Use this optional parameter to display information about an event notification destination that has the specified syslog timestamp format override.

**[-syslog-hostname-format-override {no-override|fqdn|hostname-only}] - Syslog Hostname Format Override**

Use this optional parameter to display information about an event notification destination that has the specified syslog hostname format override.

## Examples

The following shows examples of "event notification destination show":

```
cluster1::> event notification destination show
```

Name	Type	Destination
StorageAdminEmail	email	StorageAdmin@example.com (via "localhost" from "admin@localhost", configured in "event config")
StorageAdminSyslog	syslog	example.com (port: 514, transport: udp-unencrypted)
snmp-traphost	snmp	10.30.40.10 (from "system snmp traphost")
RestApi	rest-api	https://rest.example.com/rest

4 entries were displayed.

```
cluster1::> event notification destination show -type snmp -instance
```

```
Destination Name: snmp-traphost
      Type of Destination: snmp
      Destination: 10.30.40.10 (from "system snmp traphost")
Server CA Certificates Present?: -
Client Certificate Issuing CA: -
Client Certificate Serial Number: -
Client Certificate Valid?: -
      Syslog Port: -
      Syslog Transport: -
      Syslog Message Format: -
Syslog Timestamp Format Override: -
Syslog Hostname Format Override: -
```

## Related Links

- [event notification destination create](#)
- [security config ocsp show](#)

# event notification history show

Display latest events sent to destination

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **event notification history show** command displays a list of event messages that have been sent to a notification destination. Information displayed by the command for each event is identical to that of the event log show command. This command displays events sent to a notification destination while the event log show command displays all events that have been logged.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[ [-instance ] ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**-destination <text> - Destination**

Specifies the destination to which event messages have been sent to be displayed.

**[-node {<nodename>|local}] - Node**

Displays a list of events for the node you specify. Use this parameter with the **-seqnum** parameter to display detailed information.

**[-seqnum <Sequence Number>] - Sequence#**

Selects the events that match this parameter value. Use with the **-node** parameter to display detailed information.

**[-time <MM/DD/YYYY HH:MM:SS>] - Time**

Selects the events that match this parameter value. Use the format: MM/DD/YYYY HH:MM:SS [+HH:MM]. You can specify a time range by using the ".." operator between two time statements.

**[-severity {EMERGENCY|ALERT|ERROR|NOTICE|INFORMATIONAL|DEBUG}] - Severity**

Selects the events that match this parameter value. Severity levels are as follows:

- EMERGENCY - Disruption.
- ALERT - Single point of failure.
- ERROR - Degradation.
- NOTICE - Information.
- INFORMATIONAL - Information.
- DEBUG - Debug information.

**[-message-name <Message Name>] - Message Name**

Selects the events that match this parameter value (string). Message names are descriptive, so filtering output by message name displays messages of a specific type.

**[-event <text>] - Event**

Selects the events that match this parameter value. This parameter is useful when entered with wildcards. The "event" field contains the full text of the event, including any parameters. For example, the wafl.vol.offline event displays the name of the volume that is taken offline.

**Examples**

The following example displays all the events which match "important-events" filter and forwarded to the "snmp-traphost" destination:

```
cluster1::> event filter show
Filter Name Rule      Rule      Message Name      SNMP Trap Type  Severity
      Position Type
-----
default-trap-events
      1      include  *          *                  EMERGENCY, ALERT
      2      include  *          Standard, Built-in
      3      exclude *          *                  *
important-events
      1      include  *          *                  EMERGENCY, ALERT
      2      include  callhome.* *                  ERROR
      3      exclude *          *                  *
no-info-debug-events
      1      include  *          *                  EMERGENCY,
ALERT, ERROR, NOTICE
      2      exclude *          *                  *
8 entries were displayed.

cluster1::> event notification destination show
Name      Type      Destination
-----
snmp-traphost  snmp      192.168.10.40 (from "system snmp traphost")

cluster1::> event notification show

-----
1      important-events snmp-traphost

cluster1::>event notification history show -destination snmp-traphost
Time      Node      Severity      Event
-----
5/14/2015 03:02:09 node1      EMERGENCY      callhome.clam.node.oog: Call home
for NODE(S) OUT OF CLUSTER QUORUM.
5/13/2015 12:05:45 node1      ALERT          od.rdb.mbox.read.error:
message="RDB-HA readPSlot: Failed to read blob_type 19, (pslot 16), instance 1: 1
(1)."
```

2 entries were displayed.

# event status show

Display event status

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **event status show** command summarizes information about occurrences of events. For detailed information about specific occurrences of events, use the [event log show](#) command.

## Parameters

**{ [-fields <fieldname>,...]**

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[-instance ]}**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node**

Selects the event records that match this parameter value. Events are tracked on a node-by-node basis, rather than being rolled up cluster-wide.

**[-message-name <Message Name>] - Message Name**

Selects the event records that match this parameter value. The message name is a short descriptive string. Filtering output by message name displays messages of a specific type.

**[-indications <integer>] - Number of Indications**

Selects the event records that match this parameter value. This parameter is most useful when used with a range, such as using the range ">20" to display only events that have been posted more than 20 times.

**[-drops <integer>] - Number of Drops**

Selects the event records that match this parameter value.

**[-last-time-occurred <MM/DD/YYYY HH:MM:SS>] - Last Indication Time**

Selects the event records that match this parameter value.

**[-last-time-dropped <MM/DD/YYYY HH:MM:SS>] - Last Suppressed Indication Time**

Selects the event records that match this parameter value.

**[-last-time-processed <MM/DD/YYYY HH:MM:SS>] - Last Processed Indication Time**

Selects the event records that match this parameter value.

**[-stat-starting-time <MM/DD/YYYY HH:MM:SS>] - Stat Starting Time**

Selects the event records that match this parameter value.

**[-last-hour-histogram <integer>,...] - 60-minute Histogram**

Use this parameter with the **-fields** parameter to display the "last hour" histogram for each event type. The last hour histogram records the number of times each event occurred in the last hour. The histogram is divided into sixty buckets, and each bucket collects one minute's events. The buckets display with the most recent event first.

**[-last-day-histogram <integer>,...] - 24-hour Histogram**

Use this parameter with the **-fields** parameter to display the "last day" histogram for each event type. The last day histogram records the number of times each event occurred in the last day. The histogram is divided into 24 buckets, and each bucket collects one hour's events. The buckets display with the most recent event first.

**[-last-week-histogram <integer>,...] - 7-day Histogram**

Use this parameter with the **-fields** parameter to display the "last week" histogram for each event type. The last week histogram records the number of times each event occurred in the last week. The histogram is divided into 7 buckets, and each bucket collects one day's events. The buckets display with the most recent event first.

**[-severity {NODE\_FAULT|SVC\_FAULT|NODE\_ERROR|SVC\_ERROR|WARNING|NOTICE|INFO|DEBUG|VAR}] - Severity**

Selects events that have the event severity you specify. Severity levels sort with the most severe levels first. Severity levels:

- **NODE\_FAULT** - The node has detected data corruption, or is unable to provide client service.
- **SVC\_FAULT** - The node has detected a temporary loss of service. Typically, this is caused by a transient software fault.
- **NODE\_ERROR** - The node has detected a hardware error that is not immediately fatal.
- **SVC\_ERROR** - The node has detected a software error that is not immediately fatal.
- **WARNING** - A high-priority message that does not indicate a fault.
- **NOTICE** - A normal-priority message that does not indicate a fault.
- **INFO** - A low-priority message that does not indicate a fault.
- **DEBUG** - A debugging message. These messages are typically suppressed.
- **VAR** - These messages have variable severity. Severity level for these messages is selected at runtime.

The examples below illustrate how to query on severity.

## Examples

The following example displays recent event-occurrence status for node1:

```
cluster1::> event status show -node node1
Node          Message          Occurs Drops Last Time
```

node1	raid.spares.media_scrub.start	6	0	3/11/2010 15:59:00
node1	raid.uninitialized.parity.vol	3	0	3/11/2010 15:58:28
node1	raid.vol.state.online	3	0	3/11/2010 15:58:29
node1	reg.defaultCommit.set.timeTaken	1	0	3/11/2010 15:58:28
node1	scsitgt.ha.state.changed	2	0	3/11/2010 15:58:28
node1	ses.multipath.notSupported	2	0	3/11/2010 15:58:43
node1	shelf.config.mpha	1	0	3/11/2010 15:58:48
node1	sk.hog.runtime	1	0	3/11/2010 15:58:28
node1	snmp.agent.msg.access.denied	1	0	3/11/2010 15:58:28
node1	snmp.link.up	6	0	3/11/2010 15:58:28
node1	tar.csum.mismatch	2	0	3/11/2010 15:58:28
node1	tar.extract.success	2	0	3/11/2010 15:58:28
node1	vifmgr.lifsuccessfullymoved	3	0	3/11/2010 15:58:46
node1	vifmgr.portdown	1	0	3/11/2010 15:58:48
node1	vifmgr.portup	5	0	3/11/2010 15:58:48
node1	vifmgr.startedsuccessfully	1	0	3/11/2010 15:58:43

The following example displays a summary of events which are warnings or more severe:

```
cluster1::> event status show -node node1 -severity <=warning -fields
indications,drops,severity
node  message-name                indications drops severity
-----
node1  api.output.invalidSchema  5463      840  WARNING
node1  callhome.dsk.config        1          0  WARNING
node1  callhome.sys.config        1          0  SVC_ERROR
node1  cecc_log.dropped           145        0  WARNING
node1  cecc_log.entry              5          0  WARNING
node1  cecc_log.entry_no_syslog  4540      218  WARNING
node1  cecc_log.summary           5          0  WARNING
node1  cf.fm.noPartnerVariable   5469      839  WARNING
node1  cf.fm.notkoverBadMbox     1          0  WARNING
node1  cf.fm.notkoverClusterDisable 1          0  WARNING
node1  cf.fsm.backupMailboxError  1          0  WARNING
node1  cf.takeover.disabled       23         0  WARNING
node1  cmds.sysconf.logErr        1          0  NODE_ERROR
node1  config.noPartnerDisks      1          0  NODE_ERROR
node1  fci.initialization.failed  2          0  NODE_ERROR
node1  fcp.service.adapter        1          0  WARNING
node1  fmm.BlobNotFound           1          0  WARNING
node1  ha.takeoverImpNotDef       1          0  WARNING
node1  httpd.config.mime.missing  2          0  WARNING
node1  mgr.opsmgr.autoreg.norec   1          0  WARNING
node1  monitor.globalStatus.critical 1          0  NODE_ERROR
node1  raid.mirror.vote.versionZero 1          0  SVC_ERROR
node1  ses.multipath.notSupported  2          0  NODE_ERROR
```

```
node1 snmp.agent.msg.access.denied 1 0 WARNING
24 entries were displayed.
```

The above example makes use of several features which are common to all **show** commands:

- A query is specified for the severity parameter. A query restricts the output of the show command; only rows matching the query will be displayed. In this case, the query indicates that only events which have a severity of "WARNING" or more severe will be displayed.
- The fields parameter selects the fields to display. Note that the severity field is not displayed in the default output.

# job delete

Delete a job

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **job delete** command deletes a job. Use the [job show](#) command to view a list of running jobs that can be deleted.

## Parameters

**-id <integer>** - Job ID

The numeric ID of the job you want to delete. A job ID is a positive integer.

**[-vserver <vserver name>]** - Owing Vserver

Use this parameter to specify the name of the Vserver that owns the job.

## Examples

The following example deletes the job that has ID 99:

```
cluster1::> job delete -id 99
```

## Related Links

- [job show](#)

# job pause

Pause a job

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **job pause** command pauses a job. Use the [job resume](#) command to resume a paused job. Use the [job show](#) command to view a list of running jobs that can be paused.

## Parameters

**-id <integer>** - Job ID

The numeric ID of the job you want to pause. A job ID is a positive integer.

**[-vserver <vserver name>]** - Owing Vserver

Use this parameter to specify the name of the Vserver that owns the job.

## Examples

The following example pauses the job that has ID 183:

```
cluster1::> job pause -id 183
```

## Related Links

- [job resume](#)
- [job show](#)

# job resume

Resume a job

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `job resume` command resumes a job that was previously paused by using the `job pause` command. Use the `job show` command to view a list of paused jobs that can be resumed.

## Parameters

**-id <integer>** - Job ID

The numeric ID of the paused job to be resumed. A job ID is a positive integer.

**[-vserver <vserver name>]** - Owing Vserver

Use this parameter to specify the name of the Vserver that owns the job.

## Examples

The following example resumes the paused job that has ID 183:

```
cluster1::> job resume -id 183
```

## Related Links

- [job pause](#)

# job show-bynode

Display a list of jobs by node

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `job show-bynode` command displays information about jobs on a per-node basis. The command output depends on the parameters specified with the command. If no parameters are specified, the command displays information about all jobs in the cluster that are currently owned by a node.

To display detailed information about a specific job, run the command with the `-id` parameter. The detailed view includes all of the default information plus additional items.

You can specify additional parameters to display only information that matches the values you specify for those parameters. For example, to display information only about jobs running on a specific node, run the command with the `-node` parameter.

## Parameters

### {[-fields <fieldname>,...]}

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

### ![-instance ]}

If you specify the **-instance** parameter, the command displays detailed information about all fields.

### [-node {<nodename>|local}] - Node

Use this parameter to display information only about the jobs that are associated with the node you specify.

### [-id <integer>] - Job ID

Use this parameter to display information only about the jobs that match the ID or range of IDs you specify.

### [-vserver <vserver name>] - Owing Vserver

Use this parameter with the name of a Vserver to display only jobs that are owned by that Vserver.

### [-name <text>] - Name

Use this parameter to display information only about the jobs that match the job name you specify.

### [-description <text>] - Description

Use this parameter to display information only about the jobs that match the description you specify.

### [-affinity {Cluster|Node}] - Affinity

Use this parameter with an affinity value to display only jobs that match the affinity you specify.

### [-username <text>] - User Name

Use this parameter with a username to display only jobs that are associated with that user.

## Examples

The following example displays information about all jobs on a per-node basis:

```
node::> job show-bynode
```

Node	Job ID	Name	Owing Vserver	Affinity
node0	1501	log-rotation	node-vserver	Cluster
		Descr:logrotation job		

```

node1      1498  log-rotation  node-vserver
              Cluster
              Descr:logrotation job
node2      1499  log-rotation  node-vserver
              Cluster
              Descr:logrotation job
node3      1500  log-rotation  node-vserver
              Cluster
              Descr:logrotation job

```

## job show-cluster

Display a list of cluster jobs

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

### Description

The **job show-cluster** command displays information about cluster-affiliated jobs. The command output depends on the parameters specified with the command. If no parameters are specified, the command displays information about all cluster-affiliated jobs.

To display detailed information about a specific job, run the command with the **-id** parameter. The detailed view includes all of the default information plus additional items.

You can specify additional parameters to display only information that matches the values you specify for those parameters. For example, to display information only about jobs running on a specific node, run the command with the **-node** parameter.

### Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ [-instance ] ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-id <integer>] - Job ID**

Use this parameter to display information only about the jobs that match the ID or range of IDs you specify.

**[-vserver <vserver name>] - Owning Vserver**

Use this parameter with the name of a Vserver to display only jobs that are owned by that

Vserver.

**[-name <text>] - Name**

Use this parameter to display information only about the jobs that match the job name you specify.

**[-description <text>] - Description**

Use this parameter to display information only about the jobs that match the description you specify.

**[-priority {Low|Medium|High|Exclusive}] - Priority**

Use this parameter to display information only about the jobs that match the priority you specify.

**[-node <nodename>] - Node**

Use this parameter to display information only about the jobs that are associated with the node you specify.

**[-affinity {Cluster|Node}] - Affinity**

Use this parameter with an affinity value to display only jobs that match the affinity you specify.

**[-schedule <job\_schedule>] - Schedule**

Use this parameter to display information only about the jobs that run on the schedule you specify.

**[-queuetime <MM/DD HH:MM:SS>] - Queue Time**

Use this parameter to display information only about the jobs that match the queue time you specify.

**[-starttime <MM/DD HH:MM:SS>] - Start Time**

Use this parameter to display information only about the jobs that match the start time you specify.

**[-endtime <MM/DD HH:MM:SS>] - End Time**

Use this parameter to display information only about the jobs that match the end time you specify.

**[-dropdeadtime <MM/DD HH:MM:SS>] - Drop-dead Time**

Use this parameter to display information only about the jobs that match the final timeout time you specify.

**[-restarted {true|false}] - Restarted?**

Use this parameter to display information only about the jobs that match the restart value you specify.

**[-state**

**{Initial|Queued|Running|Waiting|Pausing|Paused|Quitting|Success|Failure|Reschedule|Error|Quit|Dead|Unknown|Restart|Dormant}] - State**

Use this parameter to display information only about the jobs that match the job state you

specify.

### **[-code <integer>] - Status Code**

Use this parameter to display information only about the jobs that match the status code you specify.

### **[-completion <text>] - Completion String**

Use this parameter to display information only about the jobs that match the completion text you specify.

### **[-jobtype <text>] - Job Type**

Use this parameter to display information only about the jobs that match the job type you specify.

### **[-category <text>] - Job Category**

Use this parameter to display information only about the jobs that match the job category you specify.

### **[-uuid <UUID>] - UUID**

Use this parameter to display information only about the jobs that match the UUID you specify.

### **[-username <text>] - User Name**

Use this parameter with a username to display only jobs that are associated with the user you specify.

## Examples

The following example displays information about all cluster-affiliated jobs:

```
cluster1::> job show-cluster
```

Job ID	Name	Owning Vserver	Node	State
305	Auto_Mirror	node-vserver	-	Running
6202	mirror-03_10	node-vserver	-	Queued
	Descr:Auto mirror			
6203	mirror-04_10	node-vserver	-	Queued
	Descr:Auto mirror			
6204	mirror-01_10	node-vserver	-	Queued
	Descr:Auto mirror			
6205	mirror-02_10	node-vserver	-	Queued
	Descr:Auto mirror			
6206	mirror-05_10	node-vserver	-	Queued

Descr:Auto mirror

# job show-completed

Display a list of completed jobs

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **job show-completed** command displays information about completed jobs. The command output depends on the parameters you specify with the command. If you do not use any parameters, the command displays information about all completed jobs.

To display detailed information about a specific job, run the command with the **-id** parameter. The detailed view includes all of the default information plus additional items.

You can specify additional parameters to display only information that matches those parameters. For instance, to display information only about jobs running on a specific node, run the command with the **-node** parameter.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[ [-instance ] ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-id <integer>] - Job ID**

Use this parameter to display information only about the jobs that match the ID or range of IDs you specify.

**[-vserver <vserver name>] - Owning Vserver**

Use this parameter with the name of a Vserver to display only jobs that are owned by that Vserver.

**[-name <text>] - Name**

Use this parameter to display information only about the jobs that match the name you specify.

**[-description <text>] - Description**

Use this parameter to display information only about the jobs that match the description you specify.

**[-priority {Low|Medium|High|Exclusive}] - Priority**

Use this parameter to display information only about the jobs that match the priority you specify.

**[-node <nodename>] - Node**

Use this parameter to display information only about the jobs that are associated with the node you specify.

**[-affinity {Cluster|Node}] - Affinity**

Use this parameter with an affinity value to display only jobs that match the affinity you specify.

**[-schedule <job\_schedule>] - Schedule**

If you use this parameter, the command displays information only about the jobs that have the schedule you specify.

**[-queuetime <MM/DD HH:MM:SS>] - Queue Time**

If you use this parameter, the command displays information only about the jobs that have the queue time you specify.

**[-starttime <MM/DD HH:MM:SS>] - Start Time**

Use this parameter to display information only about the jobs that have the start time you specify.

**[-endtime <MM/DD HH:MM:SS>] - End Time**

Use this parameter to display information only about the jobs that have the end time you specify.

**[-dropdeadtime <MM/DD HH:MM:SS>] - Drop-dead Time**

Use this parameter to display information only about the jobs that time out at the time you specify.

**[-restarted {true|false}] - Restarted?**

Use this parameter to display information only about the jobs that match the restart value you specify.

**[-state**

**{Initial|Queued|Running|Waiting|Pausing|Paused|Quitting|Success|Failure|Reschedule|Error|Quit|Dead|Unknown|Restart|Dormant}] - State**

Use this parameter to display information only about the jobs that match the job state you specify.

**[-code <integer>] - Status Code**

Use this parameter to display information only about the jobs that match the status code you specify.

**[-completion <text>] - Completion String**

Use this parameter to display information only about the jobs that match the completion text you specify.

**[-jobtype <text>] - Job Type**

Use this parameter to display information only about the jobs that match the job type you specify.

**[-category <text>] - Job Category**

Use this parameter to display information only about the jobs that match the job category you specify.

**[-uuid <UUID>] - UUID**

Use this parameter to display information only about the jobs that match the UUID you specify.

**[-username <text>] - User Name**

Use this parameter with a username to display only jobs that are associated with that user.

## Examples

The following example displays information about all completed jobs:

```
node::> job show-completed
Job ID Name          Owing
                    Vserver  End Time      Code      Completion String
-----
305   Auto_Mirror      node-vserver
                    10/10 08:07:05 0          Succeeded
6202  mirror-03_10     node-vserver
                    10/10 11:10:07 0
6203  mirror-04_10     node-vserver
                    10/10 12:10:09 0
6204  mirror-01_10     node-vserver
                    10/10 09:10:03 0
6205  mirror-02_10     node-vserver
                    10/10 10:10:08 0
6206  mirror-05_10     node-vserver
                    10/10 05:10:04 0
```

## job show

Display a list of jobs

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **job show** command displays information about jobs. By default, the command displays information about all current jobs.

To display detailed information about a specific job, run the command with the **-id** parameter.

You can specify additional parameters to select information that matches the values you specify for those parameters. For example, to display information only about jobs running on a specific node, run the command with the **-node** parameter.

## Parameters

### { [-fields <fieldname>, ... ]

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

### [ [-inprogress ]

Displays the job ID, the job name, the owning Vserver, and the progress of the job.

### [ [-jobstate ]

Displays information about each job's state, including the queue state, whether the job was restarted, and when the job has completely timed out.

### [ [-sched ]

Displays the job ID, the job name, the owning Vserver, and the schedule on which the job runs.

### [ [-times ]

Displays the job ID, the job name, the owning Vserver, the time when the job was last queued, the time when the job was last started, and the time when the job most recently ended.

### [ [-type ]

Displays the job ID, the job name, the job type, and the job category.

### [ [-jobuuid ]

Displays the job ID, the job name, the owning Vserver, and the job UUID.

### [ [-instance ] }

If you specify the **-instance** parameter, the command displays detailed information about all fields.

### [ -id <integer> ] - Job ID

Selects the jobs that match the ID or range of IDs that you specify.

### [ -vserver <vserver name> ] - Owning Vserver

Selects jobs that are owned by the specified Vserver.

### [ -name <text> ] - Name

Selects the jobs that match this parameter value.

### [ -description <text> ] - Description

Selects the jobs that match this parameter value.

**[-priority {Low|Medium|High|Exclusive}] - Priority**

Selects the jobs that match this parameter value.

**[-node <nodename>] - Node**

Selects the jobs that match this parameter value.

**[-affinity {Cluster|Node}] - Affinity**

Selects the jobs that match this parameter value.

**[-schedule <job\_schedule>] - Schedule**

Selects the jobs that match this parameter value.

**[-queuetime <MM/DD HH:MM:SS>] - Queue Time**

Selects the jobs that match this parameter value.

**[-starttime <MM/DD HH:MM:SS>] - Start Time**

Selects the jobs that match this parameter value.

**[-endtime <MM/DD HH:MM:SS>] - End Time**

Selects the jobs that match this parameter value.

**[-dropdeadtime <MM/DD HH:MM:SS>] - Drop-dead Time**

Selects the jobs that match this parameter value.

**[-restarted {true|false}] - Restarted?**

Selects the jobs that match this parameter value.

**[-state**

**{Initial|Queued|Running|Waiting|Pausing|Paused|Quitting|Success|Failure|Reschedule|Error|Quit|Dead|Unknown|Restart|Dormant}] - State**

Selects the jobs that match this parameter value.

**[-code <integer>] - Status Code**

Selects the jobs that match this parameter value.

**[-completion <text>] - Completion String**

Selects the jobs that match this parameter value.

**[-jobtype <text>] - Job Type**

Selects the jobs that match this parameter value.

**[-category <text>] - Job Category**

Selects the jobs that match this parameter value.

**[-uuid <UUID>] - UUID**

Selects the jobs that match this parameter value.

**[-progress <text>] - Execution Progress**

Selects the jobs that match this parameter value.

**[-username <text>] - User Name**

Selects the jobs that match this parameter value.

**[-restart-is-delayed-by-module <text>] - Restart Is Delayed by Module**

Selects jobs which are or were delayed by the specified module during the restart. For example:  
MCC\_SWITCHBACK

## Examples

The following example displays information about all jobs on the node named node1:

```
cluster1::> job show -node node1
      Owing
Job ID Name          Vserver  Node      State
-----
308114 mirror-daily-3587206
           node-vserver
                   node1      Running
      Descr:Auto-replicate to 1 mirror(s)
308115 mirror-daily-3618985
           node-vserver
                   node1      Running
      Descr:Auto-replicate to 1 mirror(s)
308116 mirror-daily-3619010
           node-vserver
                   node1      Queued
      Descr:Auto-replicate to 1 mirror(s)
308117 mirror-daily-3749547
           node-vserver
                   node1      Queued
      Descr:Auto-replicate to 1 mirror(s)
4 entries were displayed.
```

## job stop

Stop a job

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **job stop** command stops a running job. A stopped job cannot be resumed. Use the [job pause](#)

command to pause a job so that you can later resume it. Use the [job show](#) command to view a list of running jobs.

## Parameters

**-id <integer> - Job ID**

The numeric ID of the job to stop. A job ID is a positive integer.

**[-vserver <vserver name>] - Owing Vserver**

Use this parameter to specify the name of the Vserver that owns the job.

## Examples

The following example stops the job that has ID 101:

```
cluster1::> job stop -id 101
```

## Related Links

- [job pause](#)
- [job show](#)

# job unclaim

Unclaim a cluster job

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

The **job unclaim** command causes a cluster-affiliated job that is owned by an unavailable node to be unclaimed by that node. Another node in the cluster can then take ownership of the job. Use the [job show-cluster](#) command to obtain a list of cluster-affiliated jobs.

## Parameters

**-id <integer> - Job ID**

Use this parameter to specify the ID number of the job to unclaim.

**[-vserver <vserver name>] - Owing Vserver**

Use this parameter to specify the name of the Vserver that owns the job.

## Examples

The following example shows how to unclaim the cluster-affiliated job with the ID **27** that is owned by the Vserver **vs1** :

```
cluster1::*> job unclaim -vserver vs1 -id 27
```

## Related Links

- [job show-cluster](#)

# job watch-progress

Watch the progress of a job

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **job watch-progress** command displays the progress of a job, and periodically updates that display. You can specify the frequency of the updates.

## Parameters

**-id <integer>** - Job ID

Use this parameter to specify the numeric ID of the job to monitor.

**[-vserver <vserver name>]** - Owing Vserver

Use this parameter to specify the name of the Vserver that owns the job.

**[-interval <integer>]** - Refresh Interval (seconds)

Use this parameter to specify the number of seconds between updates.

## Examples

The following example show how to monitor the progress of the job that has ID **222** on Vserver **vs0** . The progress display updates every 3 seconds.

```
cluster1::> job watch-progress -vserver vs0 -id 222 -interval 3
```

# job history show

Display a history of jobs

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **job history show** command displays a history of completed jobs with newer entries displayed first. You can specify optional parameters to select information about job history items that match only those parameters. For example, to display information about jobs that were completed on February 27 at noon, run the command with **-endtime "02/27 12:00:00"**.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[ -node {<nodename>|local} ] - Node**

Selects the completed jobs that match this parameter value.

**[ -record <Sequence Number> ] - Record ID**

Selects the completed jobs that match the record ID or range of record IDs you specify. Note that record IDs are unique for each node, not for the cluster as a whole. As a result, there can be two records with the same record ID within the cluster.

**[ -vserver <vserver name> ] - Owing Vserver**

Selects the completed jobs that are owned by the Vserver you specify.

**[ -id <integer> ] - Job ID**

Selects the completed jobs that match this parameter value.

**[ -endtime <MM/DD HH:MM:SS> ] - End Time**

Selects jobs that completed at the time you specify. This parameter is most useful when used with a range of times.

**[ -starttime <MM/DD HH:MM:SS> ] - Start Time**

Selects completed jobs that were started at the time you specify. This parameter is most useful when used with a range of times.

**[-name <text>] - Name**

Selects the completed jobs that match this parameter value.

**[-description <text>] - Description**

Selects the completed jobs that match this parameter value.

**[-code <integer>] - Status Code**

Selects the completed jobs that match this parameter value. Each job defines its own status codes. The completion text is more informative, but support technicians may request this numeric code.

**[-progress <text>] - Progress String**

Selects the completed jobs that match this parameter value.

**[-completion <text>] - Completion String**

Selects the completed jobs that match this parameter value.

**[-jobuuid <UUID>] - Job UUID**

Selects the completed jobs that match this parameter value.

**[-event-type {Idle|Running|Succeeded|Failed|Paused|Stopped|Deleted|Error}] - Event Type**

Selects the completed jobs that match this parameter value.

**[-event-time <MM/DD HH:MM:SS>] - Event Time**

Selects the completed jobs that match this parameter value. This parameter is most useful when used with a range of times.

**[-error-code <integer>] - Job Manager Error Code**

Selects the completed jobs that match this parameter value.

**[-error-text <text>] - Job Manager Error Text**

Selects the completed jobs that match this parameter value.

**[-username <text>] - User Name**

Selects the completed jobs that match this parameter value.

## Examples

The following example displays information about all completed jobs:

```
cluster1::> job history show
Time           Node           Owning
                Vserver       Name           Event          Job ID
-----
08/23 08:58:24 node1          node1-vs     Vol Create     Succeeded      76
  Description: Create testvol
  Completion: Successful
```

```
job initstate show
```

```
08/23 08:58:22 node1          node1-vs  Vol Create           Running           76
    Description: Create testvol
08/22 08:16:36 node1          node1-vs  CLUSTER BACKUP AUTO weekly
    Succeeded              4
    Description: Cluster Backup Job
08/22 08:15:49 node1          node1-vs  CLUSTER BACKUP AUTO weekly
    Running                4
    Description: Cluster Backup Job
08/22 08:15:08 node1          node1-vs  CLUSTER BACKUP AUTO weekly
    Idle                   4
    Description: Cluster Backup Job
08/22 08:15:03 node1          node1-vs  CLUSTER BACKUP AUTO weekly
    Running                4
    Description: Cluster Backup Job
6 entries were displayed.
```

The following example shows how to use a range with the "endtime" parameter to select only the events that ended between 8:15 and 8:16 on August 22nd.

```
cluster1::> job history show -endtime "08/22 08:15:00".."08/22 08:16:00"
      Owing
Time      Node      Vserver  Name              Event              Job ID
-----
08/22 08:15:49 node1     node1-vs  CLUSTER BACKUP AUTO weekly
      Running              4
    Description: Cluster Backup Job
08/22 08:15:08 node1     node1-vs  CLUSTER BACKUP AUTO weekly
      Idle                 4
    Description: Cluster Backup Job
08/22 08:15:03 node1     node1-vs  CLUSTER BACKUP AUTO weekly
      Running              4
    Description: Cluster Backup Job
3 entries were displayed.
```

## job initstate show

Display init state for job managers

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **job initstate show** command displays information about the initialization states of job-manager processes.

## Parameters

### { [-fields <fieldname>, ... ] }

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

### [ [-instance ] ] }

If you specify the **-instance** parameter, the command displays detailed information about all fields.

### [-node {<nodename>|local}] - Node

Selects the nodes that match this parameter value.

### [-process <process\_name>] - Process Name

Selects the nodes that match this parameter value.

### [-initialized {true|false}] - Initialized?

Selects the nodes that match this parameter value (**true** means initialized; **false** means not initialized).

### [-cache-root <text>] - Cache Root

Selects the nodes that match this parameter value.

### [-siteid <UUID>] - Site ID

Selects the nodes that match this parameter value.

### [-hp-threads <integer>] - High Priority Threads

Selects the nodes that have the number of high-priority threads you specify.

### [-mp-threads <integer>] - Medium Priority Threads

Selects the nodes that have the number of medium-priority threads you specify.

### [-lp-threads <integer>] - Low Priority Threads

Selects the nodes that have the number of low-priority threads you specify.

### [-tx-interval <integer>] - Transaction Interval

Selects the nodes that have the number of seconds you specify as their transaction interval.

### [-initmsg <text>] - Initialization Message

Selects the nodes that match this parameter value.

### [-thread-initmsg <text>] - Thread Initialization Message

Selects the nodes that match this parameter value. The thread initialization message contains information about thread status. If there is no information to communicate, this message is empty.

### [-recovery-enabled {true|false}] - Job Failover Enabled?

Selects the nodes that match this parameter value (**true** means enabled, **false** means not

enabled).

### **[-ex-threads <integer>] - Exclusive Priority Threads**

Selects the nodes that match this parameter value.

## Examples

The following example shows how to display general job-manager initialization-state information for a cluster.

```
cluster1::*> job initstate show
```

Node	Process	Init?	HP Thr	MP Thr	LP Thr	EX Thr	TX Int	Failover?
node1	mgwd	true	2	3	5	8	300	true
node2	mgwd	true	2	3	5	8	300	true

2 entries were displayed.

The following example shows how to display detailed job-manager initialization-state information for a node named **node0**.

```
cluster1::*> job initstate show -instance -node node0
```

```

Node: node0
Process Name: mgwd
Initialized?: true
Cache Root: /mroot/jm_cache
Site ID: 824e8f7d-f49-1d9-84af-00423b7352
High Priority Threads: 2
Medium Priority Threads: 3
Low Priority Threads: 5
Transaction Interval: 300
Initialization Message: Initialized
Are Threads Running?: -
Job Failover Enabled?: true
Exclusive Priority Threads: 8

```

## job private delete

Delete a job

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

The **job private delete** command deletes a private job. Private jobs are affiliated with a specific node and do not use any cluster facilities, such as the replicated database.

If you use this command on a job that does not support the delete operation, the command returns an error message.

Use the [job private show](#) command to view a list of private jobs that can be deleted.

## Parameters

### **-node {<nodename>|local} - Node**

Use this parameter to specify the node with which the private job is associated.

### **-id <integer> - Job ID**

Use this parameter to specify the numeric ID of the private job to be deleted. A job ID is a positive integer.

### **[-vserver <vserver name>] - Owing Vserver**

Use this parameter to specify the name of the Vserver that owns the job.

## Examples

The following example shows how to delete the job that has ID **273** from the node named **node2** :

```
cluster1::*> job private delete -node node2 -id 273
```

## Related Links

- [job private show](#)

# job private pause

Pause a job

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

The **job private pause** command pauses a private job. Private jobs are affiliated with a specific node and do not use any cluster facilities, such as the replicated database.

If you use this command to pause a job that does not support it, the command returns an error

message.

Use the [job private resume](#) command to resume a paused private job.

Use the [job private show](#) command to view a list of private jobs.

## Parameters

### **-node {<nodename>|local} - Node**

Use this parameter to specify the node with which the private job is associated.

### **-id <integer> - Job ID**

Use this parameter to specify the numeric ID of the paused private job to be resumed. A job ID is a positive integer.

### **[-vserver <vserver name>] - Owing Vserver**

Use this parameter to specify the name of the Vserver that owns the job.

## Examples

The following example pauses the private job that has ID **99** on the node **node1** :

```
cluster1::*> jobs private pause -node node1 -id 99
```

## Related Links

- [job private resume](#)
- [job private show](#)

# job private resume

Resume a job

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

The **job private resume** command resumes a private job that was paused by using the [job private pause](#) command. Private jobs are affiliated with a specific node and do not use any cluster facilities, such as the replicated database.

Use the [job private show](#) command to view a list of paused private jobs that can be resumed.

## Parameters

### **-node {<nodename>|local} - Node**

Use this parameter to specify the node with which the paused private job is associated.

### **-id <integer> - Job ID**

Use this parameter to specify the numeric ID of the paused private job to be resumed. A job ID is a positive integer.

### **[-vserver <vserver name>] - Owing Vserver**

Use this parameter to specify the name of the Vserver that owns the job.

## Examples

The following example resumes the paused private job that has ID **99** on a node named **node2** :

```
cluster1::*> job private resume -node node2 -id 99
```

# job private show-completed

Display a list of completed jobs

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

The **job private show-completed** command displays information about completed private jobs. Private jobs are affiliated with a specific node and do not use any cluster facilities, such as the replicated database.

## Parameters

{ [-fields <fieldname>,...]

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[`-instance`] }**

If you specify the `-instance` parameter, the command displays detailed information about all fields.

**[`-node` {<nodename>|local}] - Node**

Use this parameter to display information only about completed jobs that are associated with the node you specify.

**[`-id` <integer>] - Job ID**

Use this parameter to display information only about completed jobs that have the ID you specify.

**[`-vserver` <vserver name>] - Owning Vserver**

Use this parameter to display only completed jobs that are owned by the Vserver you specify.

**[`-name` <text>] - Name**

Use this parameter to display information only about completed jobs that have the name you specify.

**[`-description` <text>] - Description**

Use this parameter to display information only about completed jobs that have the description you specify.

**[`-priority` {Low|Medium|High|Exclusive}] - Priority**

Use this parameter to display information only about completed jobs that have the priority you specify.

**[`-schedule` <job\_schedule>] - Schedule**

Use this parameter to display information only about completed jobs that have the schedule you specify.

**[`-queuetime` <MM/DD HH:MM:SS>] - Queue Time**

Use this parameter to display information only about completed jobs that have the queue time you specify.

**[`-starttime` <MM/DD HH:MM:SS>] - Start Time**

Use this parameter to display information only about completed jobs that have the start time you specify.

**[`-endtime` <MM/DD HH:MM:SS>] - End Time**

Use this parameter to display information only about completed jobs that have the end time you specify.

**[`-dropdeadtime` <MM/DD HH:MM:SS>] - Drop-dead Time**

Use this parameter to display information only about completed jobs that have the final timeout time you specify.

**[-restarted {true|false}] - Restarted?**

Use this parameter to display information only about completed jobs that have the restart value you specify.

**[-state**

**{Initial|Queued|Running|Waiting|Pausing|Paused|Quitting|Success|Failure|Reschedule|Error|Quit|Dead|Unknown|Restart|Dormant}] - State**

Use this parameter to display information only about completed jobs that have the job state you specify.

**[-code <integer>] - Status Code**

Use this parameter to display information only about completed jobs that have the status code you specify.

**[-completion <text>] - Completion String**

Use this parameter to display information only about completed jobs that have the completion text you specify.

**[-jobtype <text>] - Job Type**

Use this parameter to display information only about completed jobs that have the job type you specify.

**[-category <text>] - Job Category**

Use this parameter to display information only about completed jobs that have the job category you specify.

**[-uuid <UUID>] - UUID**

Use this parameter to display information only about completed jobs that have the UUID you specify.

**[-username <text>] - User Name**

Use this parameter to display information only about completed jobs that are associated with the user you specify.

## Examples

The following example shows how to display information about all completed private jobs on the node named **node1** :

```
cluster1::*> job private show-completed -node node1
```

```
Node: node1
```

Job ID	Name	Owning Vserver	End Time	Code	Completion String
1	sync task	node1	02/17 15:03:23	0	
2	load_balancing	node1	02/17 16:29:28	0	DONE_VIF_STATS
3	snap-hourly	node1	02/17 16:05:00	0	

```

4      snap-daily      node1      02/17 00:10:00 0
5      snap-weekly    node1      02/13 00:15:00 0
8      Cross-Cluster Manager node1 02/17 16:27:27 0      complete
9      reconcile service policy node1 02/17 15:03:12 0
7 entries were displayed.
```

## job private show

Display a list of jobs

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

The **job private show** command displays information about private jobs. Private jobs are affiliated with a specific node and do not use any cluster facilities, such as the replicated database.

## Parameters

{ [-fields <fieldname>, ... ]

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

| [-inprogress ]

Displays the job ID, name, owning Vserver, and progress of each private job.

| [-jobstate ]

Displays information about each private job's state, including the queue state, whether the job was restarted, and when the job has timed out.

| [-jobuuid ]

Displays the ID, name, owning Vserver, and UUID of each private job.

| [-sched ]

Displays the job ID, name, owning Vserver, and run schedule of each private job.

| [-times ]

Displays the queue time, start time, and end time of each private job.

| [-type ]

Displays the type and category of each private job.

| [-instance ] }

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node**

Selects the private jobs that match this parameter value. .

**[-id <integer>] - Job ID**

Selects the private jobs that match the ID or range of IDs that you specify.

**[-vserver <vserver name>] - Owning Vserver**

Selects the private jobs that match this parameter value.

**[-name <text>] - Name**

Selects the private jobs that match this parameter value.

**[-description <text>] - Description**

Selects the private jobs that match this parameter value.

**[-priority {Low|Medium|High|Exclusive}] - Priority**

Selects the private jobs that match this parameter value.

**[-schedule <job\_schedule>] - Schedule**

Selects the private jobs that match this parameter value.

**[-queuetime <MM/DD HH:MM:SS>] - Queue Time**

Selects the private jobs that match this parameter value.

**[-starttime <MM/DD HH:MM:SS>] - Start Time**

Selects the private jobs that match this parameter value.

**[-endtime <MM/DD HH:MM:SS>] - End Time**

Selects the private jobs that match this parameter value.

**[-dropdeadtime <MM/DD HH:MM:SS>] - Drop-dead Time**

Selects the private jobs that match this parameter value.

**[-restarted {true|false}] - Restarted?**

Selects the private jobs that match this parameter value.

**[-state**

{Initial|Queued|Running|Waiting|Pausing|Paused|Quitting|Success|Failure|Reschedule|Error|Quit|Dead|Unknown|Restart|Dormant}] - State

Selects the private jobs that match this parameter value.

**[-code <integer>] - Status Code**

Selects the private jobs that match this parameter value.

**[-completion <text>] - Completion String**

Selects the private jobs that match this parameter value.

**[-jobtype <text>] - Job Type**

Selects the private jobs that match this parameter value.

**[-category <text>] - Job Category**

Selects the private jobs that match this parameter value.

**[-uuid <UUID>] - UUID**

Selects the private jobs that match this parameter value.

**[-progress <text>] - Execution Progress**

Selects the private jobs that match this parameter value.

**[-username <text>] - User Name**

Selects the private jobs that match this parameter value.

## Examples

The following example displays information about all private jobs on the local node:

```
cluster1::*> job private show -node local
Node: node1
```

Job ID	Name	Owning Vserver	State
3	snap-hourly Description: Auto-Snapshot	cluster1	Queued
4	snap-daily Description: Auto-Snapshot	cluster1	Queued
5	snap-weekly Description: Auto-Snapshot	cluster1	Queued
6	sync task Description: sync task	cluster1	Queued
7	ldap-certs Description: ldap resync	cluster1	Queued

5 entries were displayed.

## job private stop

Stop a job

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

The **job private stop** command stops a running private job. A private job is a job that is associated

with a specific node and does not use cluster facilities. A stopped job cannot be restarted.

## Parameters

### **-node {<nodename>|local} - Node**

This specifies the node on which the job is running.

### **-id <integer> - Job ID**

This specifies the numeric ID of the job that is to be stopped.

### **[-vserver <vserver name>] - Owing Vserver**

Use this parameter to specify the name of the Vserver that owns the job.

## Examples

The following example stops a private job with the ID 416 on a node named node0:

```
cluster1::*> job private stop -node node0 -id 416
```

## job private watch-progress

Watch the progress of a job

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

The **job private watch-progress** command displays and periodically updates the progress of a private job. A private job is a job that is associated with a specific node and does not use cluster facilities. You can specify the frequency of the progress updates.

## Parameters

### **-node {<nodename>|local} - Node**

This specifies the node on which the job is running.

### **-id <integer> - Job ID**

This specifies the numeric ID of the job whose progress is to be monitored.

### **[-vserver <vserver name>] - Owing Vserver**

Use this parameter to specify the Vserver with which the paused private job is associated.

**[-interval <integer>] - Refresh Interval (seconds)**

This optionally specifies, in seconds, the frequency of the updates.

## Examples

The following example monitors the progress of the private job that has ID 127 on a node named node1. The progress is updated every 2 seconds.

```
cluster1::*> job private watch-progress -node node1 -id 127 -interval 2
Queued
```

# job schedule delete

Delete a schedule

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **job schedule delete** command deletes a schedule. Use the [job schedule show](#) command to display all current schedules.

You cannot delete any schedules that are in use by jobs. Use the [job schedule show-jobs](#) command to display jobs by schedule.

You cannot delete any schedules that are referenced by:

- Volume Snapshot copy policy entries
- SnapMirror entries
- SIS policy entries
- configuration backup settings

You must remove all references to a schedule before you can delete it. If you attempt to delete a schedule that is referenced, an error message will list which entries reference the schedule you want to delete. Use the **show** command for each of the items listed by the error message to display which entries reference the schedule. You may need to use the **-instance** parameter to display more detail.

## Parameters

**[-cluster <cluster name>] - Cluster**

This parameter specifies the name of the cluster on which you want to delete a schedule. By default, the schedule is deleted from the local cluster. In a MetroCluster configuration, the partner cluster can be specified if the local cluster is in switchover state.

**[-vserver <vserver name>] - Vserver**

This parameter specifies the name of the Vserver on which you want to delete a schedule.

**-name <text> - Schedule Name**

Use this parameter with the name of an existing schedule to specify the schedule you want to delete.

## Examples

The following example deletes a schedule named overnightbackup:

```
cluster1::> job schedule delete -name overnightbackup
```

## Related Links

- [job schedule show](#)
- [job schedule show-jobs](#)

# job schedule show-jobs

Display the list of jobs by schedule

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `job schedule show-jobs` command displays information about jobs that are associated with schedules.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

**[ [-instance ] ] }**

If you specify the `-instance` parameter, the command displays detailed information about all fields.

**[-name <text>] - Schedule Name**

Use this parameter to display information only about the jobs that are associated with the schedule you specify.

**[-affinity {Cluster|Node}] - Cluster / Node**

Use this parameter to display information only about the jobs that match the affinity value you specify.

**[-owner <text>] - Owner**

Use this parameter to display information only about the jobs that are owned by the nodes you specify.

**[-jobid <integer>] - ID**

Use this parameter to display information only about the jobs that match the ID or range of IDs that you specify.

**[-jobname <text>] - Job Name**

Use this parameter to display information only about the jobs that match the name you specify.

**[-scheduleuuid <UUID>] - Schedule Uuid**

displays the Uuid of the specific job schedule.

## Examples

The following example shows information about schedules that are associated with jobs:

```
cluster1::> job schedule show-jobs
Name          Type      Owner          Job ID   Job Name      Schedule Uuid
-----
hourly        Cluster  -              98644    mirror-hourly 8bafba5a-
ff9a-11eb-8531-005056a75903
weeklylog     Node     node0          1501     log-rotation  449c070c-
ff9a-11eb-8531-005056a75903
weeklylog     Node     node1          1498     log-rotation  8bb0adca-
ff9a-11eb-8531-005056a75903
weeklylog     Node     node2          1499     log-rotation  b15fce61-
ff9a-11eb-8531-005056a75903
weeklylog     Node     node3          1500     log-rotation  8bb14bd2-
ff9a-11eb-8531-005056a75903
5 entries were displayed.
```

## job schedule show

Display a list of available schedules

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `job schedule show` command displays information about schedules.

## Parameters

`{ [-fields <fieldname>, ... ] }`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

`[ [-instance ] ] }`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-cluster <Cluster name>] - Cluster`

Selects the schedules that match this parameter value.

`[-vserver <vserver name>] - Vserver`

Selects the schedules that match this parameter value. These job schedules can only be used by consumers in that Vserver.

`[-name <text>] - Schedule Name`

Selects the schedules that match this parameter value.

`[-type {cron|interval|builtin}] - Schedule Type`

Selects the schedules that match this parameter value.

`[-description <text>] - Description`

Selects the schedules that match this parameter value.

## Examples

The following example displays information about all schedules:

```
cluster1::> job schedule show
Cluster      Vserver      Name          Type          Description
-----
cluster1
              data_vs_1
                5min          cron
@:00,:05,:10,:15,:20,:25,:30,:35,:40,:45,:50,:55
                daily          cron          @0:10

# job schedule cron create

Create a cron schedule

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **job schedule cron create** command creates a cron schedule. A cron schedule, like a UNIX cron job, runs at a specified time. You can also specify months, days of the month, or days of the week on which the schedule will run.

If you specify values for both days of the month and days of the week, they are considered independently. For example, a cron schedule with the day specification Friday, 13 runs every Friday and on the 13th day of each month, not just on every Friday the 13th.

## Parameters

### **[-cluster <cluster name>] - Cluster**

This parameter specifies the name of the cluster on which you want to create a cron schedule. By default, the schedule is created on the local cluster. In a MetroCluster configuration, the partner cluster can be specified if the local cluster is in switchover state.

### **[-vserver <vserver name>] - Vserver**

This parameter specifies the name of the Vserver on which you want to create a cron schedule.

### **-name <text> - Name**

Use this parameter to specify the name of the cron schedule that you want to create.

### **[-month <cron\_month>, ...] - Month**

Use this parameter to specify months in which the schedule runs. Valid values are January, February, March, April, May, June, July, August, September, October, November, December, and all. Specify "all" to run the schedule every month.

### **[-dayofweek <cron\_dayofweek>, ...] - Day of Week**

Use this parameter to specify days of the week on which the schedule runs. Valid values are Sunday, Monday, Tuesday, Thursday, Friday, and Saturday, and all. Specify "all" to run the schedule every day.

### **[-day <cron\_dayofmonth>, ...] - Day**

Use this parameter to specify days of the month on which the schedule runs. Valid values range from 1 to 31.

### **[-hour <cron\_hour>, ...] - Hour**

Use this parameter to specify the hours value of the time of day at which the schedule runs. Valid

values range from 0 (midnight) to 23 (11:00 p.m.). Specify "all" to run the schedule every hour.

### **-minute <cron\_minute>,...** - Minute

Use this parameter to specify the minutes portion of the time of day at which the schedule runs. Valid values range from 0 to 59.

## Examples

The following example creates a cron schedule named weekendcron that runs on weekend days (Saturday and Sunday) at 3:00 a.m.

```
cluster1::> job schedule cron create -name weekendcron -dayofweek "Saturday, Sunday"
-hour 3 -minute 0
```

# job schedule cron delete

Delete a cron schedule

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **job schedule cron delete** command deletes a cron schedule. Use the [job schedule cron show](#) command to display all current cron schedules.

You cannot delete any cron schedules that are associated with jobs. Use the [job schedule show-jobs](#) command to display jobs by schedule.

## Parameters

### **[-cluster <cluster name>] - Cluster**

This parameter specifies the name of the cluster on which you want to delete a cron schedule. By default, the schedule is deleted from the local cluster. In a MetroCluster configuration, the partner cluster can be specified if the local cluster is in switchover state.

### **[-vserver <vserver name>] - Vserver**

This parameter specifies the name of the Vserver on which you want to delete a cron schedule.

### **-name <text> - Name**

Use this parameter with the name of an existing cron schedule to specify the cron schedule that you want to delete.

## Examples

The following example deletes a cron schedule named midnightcron:

```
cluster1::> job schedule cron delete -name midnightcron
```

- [job schedule show-jobs](#)

# job schedule cron modify

Modify a cron schedule

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **job schedule cron modify** command modifies a cron schedule. A cron schedule, like a UNIX cron job, runs at a specified time. You can also specify months, days of the month, or days of the week on which the schedule runs. Use the [job schedule cron show](#) command to display all current cron schedules. See the documentation for [job schedule cron show](#) for more information about how cron schedules work.

Modifying one parameter of a cron schedule does not affect the other parameters. For example, if cron schedule is set to run at 3:15 AM, and you modify the "hour" parameter to 4, the schedule's new time will be 4:15am. To clear a parameter of the schedule's interval, you must explicitly set that portion to "0" or "-". Some parameters can also be set to "all".

## Parameters

### **[-cluster <cluster name>] - Cluster**

Use this parameter to specify the cluster of an existing cron schedule you want to modify. The local cluster is provided as the default value. In a MetroCluster configuration, the partner cluster can be specified if the local cluster is in switchover state.

### **[-vserver <vserver name>] - Vserver**

Use this parameter to specify the Vserver of an existing cron schedule you want to modify.

### **-name <text> - Name**

Use this parameter with the name of an existing cron schedule to specify the cron schedule you want to modify.

**[-month <cron\_month>,...] - Month**

Use this parameter to specify a new "month" value for the cron schedule. Valid values are January, February, March, April, May, June, July, August, September, October, November, December, or all. Specify "all" to run the schedule every month.

**[-dayofweek <cron\_dayofweek>,...] - Day of Week**

Use this parameter to specify a new "day of week" value for the cron schedule. Valid values include Sunday, Monday, Tuesday, Thursday, Friday, Saturday, or all. Specify "all" to run the schedule every day.

**[-day <cron\_dayofmonth>,...] - Day**

Use this parameter to specify a new "day of month" value for the cron schedule. Valid values range from 1 to 31.

**[-hour <cron\_hour>,...] - Hour**

Use this parameter to specify a new "hour of the day" value for the cron schedule. Valid values range from 0 (midnight) to 23 (11:00 p.m.), Specify "all" to run the schedule every hour.

**[-minute <cron\_minute>,...] - Minute**

Use this parameter to specify a new "minute of the hour" value for the cron schedule. Valid values range from 0 to 59.

## Examples

The following example modifies a cron schedule named weekendcron so that it runs at 3:15 a.m.:

```
cluster1::> job schedule cron modify -name weekendcron -hour 3 -minute 15
```

## Related Links

- [job schedule cron show](#)

# job schedule cron show

Show cron schedules

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **job schedule cron show** command displays information about cron schedules. A cron schedule runs a job at a specified time on specified days.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[ [-instance ] ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-cluster <cluster name>] - Cluster**

Selects the cron schedules that match this parameter value.

**[-vserver <vserver name>] - Vserver**

Selects the cron schedules that match this parameter value. These job schedules can only be used by consumers in that Vserver.

**[-name <text>] - Name**

Selects the cron schedules that match this parameter value.

**[-month <cron\_month>, ...] - Month**

Selects the cron schedules that match this parameter value. Valid values are **January** , **February** , **March** , **April** , **May** , **June** , **July** , **August** , **September** , **October** , **November** , **December** , or **all** .

**[-dayofweek <cron\_dayofweek>, ...] - Day of Week**

Selects the cron schedules that match this parameter value. Valid values include **Sunday** , **Monday** , **Tuesday** , **Wednesday** , **Thursday** , **Friday** , **Saturday** , or **all** .

**[-day <cron\_dayofmonth>, ...] - Day**

Selects the cron schedules that match this parameter value. Valid values range from **1** to **31** .

**[-hour <cron\_hour>, ...] - Hour**

Selects the cron schedules that match this parameter value.

**[-minute <cron\_minute>, ...] - Minute**

Selects the cron schedules that match the minute or range of minutes that you specify.

**[-description <text>] - Description**

Selects the cron schedules that match this parameter value.

## Examples

The following example displays information about all current cron schedules:

```
cluster1::> job schedule cron show
Cluster      Vserver      Name          Description
-----
```

```

-----
cluster1
      data_vs_1
          5min      @:00,:05,:10,:15,:20,:25,:30,:35,:40,:45,:50,:55
          8hour     @2:15,10:15,18:15
          weekly    Sun@0:15

```

The following example displays information about the cron schedule named weekly:

```

cluster1::> job schedule cron show -name weekly -instance
Cluster: cluster1
  Vserver: data_vs_1
    Name: weekly
    Month: -
  Day of Week: Sunday
    Day: -
    Hour: 0
    Minute: 15
  Description: Sun@0:15

```

## job schedule interval create

Create a schedule that runs on an interval

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

### Description

The **job schedule interval create** creates an interval schedule. An interval schedule runs jobs at specified intervals after the previous job finishes. For instance, if a job uses an interval schedule of 12 hours and takes 30 minutes to complete, the job runs at the following times:

- Day one at 8:00 a.m. (the job's initial run)
- Day one at 8:30 p.m.
- Day two at 9:00 a.m.
- Day two at 9:30 p.m.

Each of the numerical parameters of the interval must be a whole number. These parameters can be used individually, or combined to define complex time values. For example, use a value of 1 day, 12 hours to create an interval of 1.5 days.

Large parameter values are converted into larger units. For example, if you create a schedule with an interval of 36 hours, the **job schedule interval show** command will display it with an interval of 1 day 12 hours.

## Parameters

### **[-cluster <cluster name>] - Cluster**

This parameter specifies the name of the cluster on which you want to create an interval schedule. By default, the schedule is created on the local cluster. In a MetroCluster configuration, the partner cluster can be specified if the local cluster is in switchover state.

### **[-vserver <vserver name>] - Vserver**

This parameter specifies the name of the Vserver on which you want to create an interval schedule.

### **-name <text> - Name**

Use this parameter to specify the name of the interval schedule you want to create.

### **[-days <integer>] - Days**

Use this parameter to specify the "days" portion of the schedule's interval. A day is one calendar day.

### **[-hours <integer>] - Hours**

Use this parameter to specify the "hours" portion of the schedule's interval.

### **[-minutes <integer>] - Minutes**

Use this parameter to specify the "minutes" portion of the schedule's interval.

### **[-seconds <integer>] - Seconds**

Use this parameter to specify the "seconds" portion of the schedule's interval.

## Examples

The following example creates an interval schedule named `rollingdaily` that runs six hours after the completion of the previous occurrence of the job:

```
cluster1::> job schedule interval create -name rollingdaily -hours 6
```

## Related Links

- [job schedule interval show](#)

# job schedule interval delete

Delete an interval schedule

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `job schedule interval delete` command deletes an interval schedule. Use the [job schedule interval show](#) command to display all current interval schedules.

You cannot delete interval schedules that are currently being run. Use the [job schedule show-jobs](#) command to display jobs by schedule.

## Parameters

### `[-cluster <cluster name>] - Cluster`

This parameter specifies the name of the cluster on which you want to delete an interval schedule. By default, the schedule is deleted from the local cluster. In a MetroCluster configuration, the partner cluster can be specified if the local cluster is in switchover state.

### `[-vserver <vserver name>] - Vserver`

This parameter specifies the name of the Vserver on which you want to delete an interval schedule.

### `-name <text> - Name`

Use this parameter with the name of an existing interval schedule to specify the interval schedule you want to delete.

## Examples

The following example deletes an interval schedule named `rollingdaily`:

```
cluster1::> job schedule interval delete -name rollingdaily
```

## Related Links

- [job schedule interval show](#)
- [job schedule show-jobs](#)

# job schedule interval modify

Modify an interval schedule

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `job schedule interval modify` command modifies an interval schedule. An interval schedule runs

jobs at a specified interval after the previous job finishes. Use the [job schedule interval show](#) command to display all current interval schedules. See the documentation of [job schedule interval show](#) for more information on how interval schedules work.

Modifying one parameter of a schedule's interval does not affect the other parameters. For example, if a schedule's interval is 1 day 12 hours, and you modify the "hours" parameter to 16, the schedule's new interval is 1 day 16 hours. To clear a parameter of the schedule's interval, you must explicitly set that parameter to "0" or "-".

## Parameters

### **[-cluster <cluster name>] - Cluster**

Use this parameter to specify the cluster of an existing interval schedule you want to modify. The local cluster is provided as the default value. In a MetroCluster configuration, the partner cluster can be specified if the local cluster is in switchover state.

### **[-vserver <vserver name>] - Vserver**

Use this parameter to specify the Vserver of an existing interval schedule you want to modify.

### **-name <text> - Name**

Use this parameter with the name of an existing interval schedule to specify the interval schedule you want to modify.

### **[-days <integer>] - Days**

Use this parameter to specify a different "days" value for the schedule's interval.

### **[-hours <integer>] - Hours**

Use this parameter to specify a different "hours" value for the schedule's interval.

### **[-minutes <integer>] - Minutes**

Use this parameter to specify a different "minutes" value for the schedule's interval.

### **[-seconds <integer>] - Seconds**

Use this parameter to specify a different "seconds" value for the schedule's interval.

## Examples

The following example sets the schedule named rollingdaily to run every eight hours:

```
cluster1::> job schedule interval modify -name rollingdaily -hours 8
```

## Related Links

- [job schedule interval show](#)

# job schedule interval show

Show interval schedules

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `job schedule interval show` command displays information about interval schedules.

## Parameters

`{ [-fields <fieldname>, ...]`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

`[-instance ]}`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-cluster <cluster name>] - Cluster`

Selects the interval schedules that match this parameter value.

`[-vserver <vserver name>] - Vserver`

Selects the interval schedules that match this parameter value. These job schedules can only be used by consumers in that Vserver.

`[-name <text>] - Name`

Selects the interval schedules that match this parameter value.

`[-days <integer>] - Days`

Selects the interval schedules that match the day value or range of values you specify.

`[-hours <integer>] - Hours`

Selects the interval schedules that match the hour value or range of values you specify.

`[-minutes <integer>] - Minutes`

Selects the interval schedules that match the minute value or range of values you specify.

`[-seconds <integer>] - Seconds`

Selects the interval schedules that match the second value or range of values you specify.

`[-description <text>] - Description`

Selects the interval schedules that match the description you specify.

## Examples

The following example displays information about all interval schedules:

```
cluster1::> job schedule interval show
Cluster      Vserver      Name          Description
-----
cluster1     data_vs_1
              rollingdaily
              Every 8h
```

## lun convert-from-namespace

Transition an existing NVMe namespace into a LUN

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

### Description

This command transitions an existing NVMe namespace in-place into a LUN within a volume in a Vserver. When performing an in-place transition, the application data remains unchanged and only the metadata gets modified.

When using this command, it is necessary that any existing maps to an NVMe subsystem for this namespace be removed first. If any maps exist for the specified namespace, you will receive an error message.

Only NVMe namespaces with a block size of 512 bytes can be transitioned into a LUN. You will receive an error message if the NVMe namespace has a block size different than 512 bytes.

### Parameters

**-vserver <Vserver Name> - Vserver Name**

The name of the Vserver containing the NVMe namespace. If only one data Vserver exists, you do not need to specify this parameter.

**-namespace-path <path> - Path of the NVMe namespace**

Specifies the path of the NVMe namespace you want to transition into LUN. Examples of correct namespace paths are **/vol/vol1/ns1** and **/vol/vol1/qtrees1/ns1**.

## Examples

```
cluster1::> lun convert-from-namespace -vserver vs1 -namespace-path /vol/vol1/ns1
```

Transitions namespace **ns1** in-place to LUN within volume **vol1** in Vserver **vs1** .

## lun create

Create a new LUN

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

### Description

This command creates a new LUN of a specific size. You cannot create a LUN at a path that already exists. You must create LUNs at the root of a volume or qtree. You can not create LUNs in the Vserver root volume.

You might find it useful to provide a meaningful path name for the LUN and containing volume. For example, you might choose a name that describes how the LUN is used, such as the name of the application, the type of data that it stores, or the user accessing the data. Examples are `/vol/database/lun0`, `/vol/finance/lun1`, and `/vol/bill/lun2`.

It is recommended that you distribute LUNs across the cluster.

When you can create a LUN, the size of the LUN could be larger than what you specified. The system generates a message if the size of the LUN is different from what you specified.

By default, when you create a LUN, it is online and it is space-reserved. Use the **lun offline** command to take a LUN offline. When you set space reserved to false, the LUN is non-space reserved.

For non-space reserved LUNs, write operations to that LUN might fail due to insufficient disk space. As a result, the host application or operating system might crash.

When you create a LUN from a file, that file cannot be deleted without deleting the LUN itself.

### Parameters

**-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver.

**{ -path <path> - LUN Path**

Specifies the path of the new LUN. The LUN path cannot contain any files. Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtree1/lun1` .

**| -volume <volume name> - Volume Name**

Specifies the volume that contains the new LUN.

**[-qtree <qtree name>] - Qtree Name**

Specifies the qtree that contains the new LUN.

**-lun <text> - LUN Name }**

Specifies the new LUN name. A LUN name is a case-sensitive name and has the following requirements:

- Must contain one to 255 characters. Spaces are not allowed.
- Can contain the letters A-Z, a-z, numbers 0-9, "-", "\_", "}", "{", and ".".

**{ -s, -size <size> - LUN Size**

Specifies the size of the LUN in bytes. You can specify a one-character multiplier suffix:

- c (1 byte)
- w (2 bytes)
- B (512 bytes)
- k (1024 bytes)
- M (k\*k bytes)
- G (k\*m bytes)
- T (m\*m bytes)

**[-use-exact-size <>true>] - Use Exact Size**

Create the LUN using the exact value specified by the **-size** parameter instead of rounding the size to best fit the LUN geometry. Size of the LUN must be a multiple of 512 bytes.

**| -f, -file-path <text> - File Path }**

Creates a LUN using the file path as the source.

**| [-foreign-disk <text>] - Foreign Disk Serial number }**

LUN is created with the same attributes (size, alignment, bytes per sector and so on) as the specified foreign disk.

**[-P, -prefix-size <size>] - Prefix Size**

Specifies the size of the prefix stream for the new LUN.

**-t, -ostype <LUN Operating System Format> - OS Type**

Specifies the OS type for the new LUN. + On an All SAN Array, the following OS types are supported:

- aix - the LUN will be used with AIX.
- hyper\_v - the LUN will be used with Microsoft Hyper-V.
- linux - the LUN will be used with Linux.

- vmware - the LUN will be used with VMware VMFS.
- windows - the LUN will be used with Microsoft Windows.

+ On all other clusters, the following OS types are supported:

- aix - the LUN will be used with AIX.
- hpux - the LUN will be used with HP-UX.
- hyper\_v - the LUN will be used with Microsoft Hyper-V.
- linux - the LUN will be used with Linux.
- netware - the LUN will be used with NetWare.
- openvms - the LUN will be used with Open-VMS.
- solaris - the LUN will be used with Solaris slice partitioning.
- solaris\_efi - the LUN will be used with Solaris EFI partitioning.
- vmware - the LUN will be used with VMware VMFS.
- windows - the LUN will be used with a Master Boot Record (MBR) partition table on Microsoft Windows 2003 or earlier.
- windows\_2008 - the LUN will be used with Microsoft Windows 2008 or later.
- windows\_gpt - the LUN will be used with a GUID Partition Type (GPT) partition table on Microsoft Windows.
- xen - the LUN will be used with Xen

#### **[-space-reserve {enabled|disabled}] - Space Reservation**

Specifies whether the space reservation setting is **enabled** or **disabled** for the new LUN. If you set the parameter to **enabled**, the LUN is space-reserved. If you set the parameter to **disabled**, the LUN is non-space reserved. The default is **enabled**.

#### **[-comment <text>] - Comment**

A description for the LUN you want to create. If the comment string contains white space, you must enclose the comment string in double quotes. The limit is 254 characters.

#### **[-space-allocation {enabled|disabled}] - Space Allocation**

Specifies the value for the space allocation attribute of the LUN. The space allocation attribute determines if the LUN supports the SCSI Thin Provisioning features defined in the Logical Block Provisioning section of the SCSI SBC-3 standard.

Specifying **enabled** for this parameter enables support for the SCSI Thin Provisioning features.

Specifying **disabled** for this parameter disables support for the SCSI Thin Provisioning features.

Hosts and file systems that do not support SCSI Thin Provisioning should not enable space allocation.

The default is **disabled**.

**[ -class {regular|protocol-endpoint|vvol} ] - Class**

Specifies the class of the new LUN. The class types are:

- regular - the LUN is for normal blocks protocol access. This is the default value.
- protocol-endpoint - the LUN is a vvol protocol endpoint.
- vvol - the LUN is a vvol data LUN.

**{ [-qos-policy-group <text>] - QoS Policy Group**

This optionally specifies which QoS policy group to apply to the LUN. This policy group defines measurable service level objectives (SLOs) that apply to the storage objects with which the policy group is associated. If you do not assign a policy group to a LUN, the system will not monitor and control the traffic to it.

If you specify this parameter for a LUN that you want to create from a file and that file belongs to a QoS policy group, Data ONTAP adds the LUN to the specified policy group and removes the file from its policy group. Both the file and the LUN that you created from the file cannot belong to QoS policy groups.

**[ -qos-adaptive-policy-group <text> ] - QoS Adaptive Policy Group }**

This optionally specifies which QoS adaptive policy group to apply to the LUN. This policy group defines measurable service level objectives (SLOs) and service level agreements (SLAs) that adjust based on the LUN's allocated space or used space.

**[ -caching-policy <text> ] - Caching Policy Name**

This optionally specifies the caching policy to apply to the LUN. A caching policy defines how the system caches this volume's data in Flash Cache modules. If a caching policy is not assigned to this LUN, the system uses the caching policy that is assigned to the containing volume or Vserver. If a caching policy is not assigned to the containing volume or Vserver, the system uses the default cluster-wide policy. The available caching policies are:

- none - Does not cache any user data or metadata blocks.
- auto - Read caches all metadata and randomly read user data blocks, and write caches all randomly overwritten user data blocks.
- meta - Read caches only metadata blocks.
- random\_read - Read caches all metadata and randomly read user data blocks.
- random\_read\_write - Read caches all metadata, randomly read and randomly written user data blocks.
- all\_read - Read caches all metadata, randomly read and sequentially read user data blocks.
- all\_read\_random\_write - Read caches all metadata, randomly read, sequentially read, and randomly written user data.
- all - Read caches all data blocks read and written. It does not do any write caching.

Default caching-policy is auto.

## Examples

```
cluster1::> lun create -vserver vs1 -path /vol/vol1/lun1 -size 100M -ostype linux
```

Creates a 100MB LUN at path **/vol/vol1/lun1** in Vserver **vs1** . The OS type is Linux, and the state is online.

## lun delete

Delete the LUN

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command deletes a LUN from a specified Vserver and volume. If the LUN is mapped and online, the force option is required to delete it.

If a LUN is mapped to an initiator group, you can unmap it by using the [lun unmap](#) command. If a LUN is online, you take it offline by using the **lun offline** command.

If you create a LUN from a file, you cannot remove the file while the LUN is linked to it. If you want to remove the file, you must first delete the LUN.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver.

**{ -path <path> - LUN Path**

Specifies the path of the LUN you want to delete. Examples of correct LUN paths are **/vol/vol1/lun1** and **/vol/vol1/qtrees1/lun1** .

**| -volume <volume name> - Volume Name**

Specifies the volume that contains the LUN you want to delete.

**[-mtree <mtree name>] - Mtree Name**

Specifies the mtree that contains the LUN you want to delete.

**-lun <text> - LUN Name }**

Specifies the LUN that you want to delete.

**[-f, -force <true>] - Force Deletion of an Online and Mapped LUN**

Force deletion of an online LUN that is mapped to an initiator group.

## **[-force-fenced <true>] - Force Deletion of a Fenced LUN**

Force deletion of a LUN that is currently fenced.

## Examples

```
cluster1::> lun delete -vserver vs1 -path /vol/vol1/lun1
```

Deletes the LUN at path /vol/vol1/lun1 on Vserver vs1.

## Related Links

- [lun unmap](#)

## lun maxsize

Display the maximum possible size of a LUN on a given volume or qtree.

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command returns the maximum size of LUNs for different OS types in a volume or qtree. The command also includes possible maximum size for LUNs with Snapshots or without Snapshots. You can specify the path of the volume or qtree to determine the maximum size of a LUN that you want to create within that volume or qtree.

If you do not specify a path, the command returns the maximum LUN size for each OS type for all volumes and qtrees in a cluster.

The available space in a volume can change over time which means that the size reported by **lun maxsize** can change as well. In addition, the maximum LUN size allowed in a [lun resize](#) command may be less than the size reported by **lun maxsize**.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**{ [-instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-vserver <Vserver Name>] - Vserver Name**

Specifies the Vserver.

**{ [-path <qtree path>] - Volume or Qtree Path**

Specifies the path of the root volume or qtree. Examples of correct volume and qtree paths are **/vol/vol1** and **/vol/vol1/qtree1**.

**[ [-volume <volume name>] - Volume Name**

Specifies the volume that contains the LUN you want to get the maximum size for.

**[-qtree <qtree name>] - Qtree Name }**

Specifies the qtree that contains the LUN you want to get the maximum size for.

**[-t, -ostype <text>] - OS Type**

Specifies the OS type for the new LUN. + On an All SAN Array, the following OS types are supported:

- aix - the LUN will be used with AIX.
- hyper\_v - the LUN will be used with Microsoft Hyper-V.
- linux - the LUN will be used with Linux.
- vmware - the LUN will be used with VMware VMFS.
- windows - the LUN will be used with Microsoft Windows.

+ On all other clusters, the following OS types are supported:

- aix - the LUN will be used with AIX.
- hpux - the LUN will be used with HP-UX.
- hyper\_v - the LUN will be used with Microsoft Hyper-V.
- linux - the LUN will be used with Linux.
- netware - the LUN will be used with NetWare.
- openvms - the LUN will be used with Open-VMS.
- solaris - the LUN will be used with Solaris slice partitioning.
- solaris\_efi - the LUN will be used with Solaris EFI partitioning.
- vmware - the LUN will be used with VMware VMFS.
- windows - the LUN will be used with a Master Boot Record (MBR) partition table on Microsoft Windows 2003 or earlier.
- windows\_2008 - the LUN will be used with Microsoft Windows 2008 or later.
- windows\_gpt - the LUN will be used with a GUID Partition Type (GPT) partition table on Microsoft Windows.
- xen - the LUN will be used with Xen

**[-complete-ss-reserve <size>] - With Complete Snapshot Reserve**

Shows the maximum size possible of a LUN if you have the complete Snapshot reserve enabled.

**[-ss-reserve <size>] - With Snapshot Reserve**

Shows the maximum size possible of a LUN if you have the Snapshot reserve enabled.

**[-without-ss-reserve <size>] - Without Snapshot Reserve**

Shows the maximum size possible of a LUN if you have no Snapshot reserve enabled.

## Examples

```
cluster1::> lun maxsize -vserver vs1 -volume vol1 -ostype linux
Virtual
Server      Volume      Qtree      OS Type    Without    With SS    Complete
            Volume      Qtree      OS Type    SS Reserve Reserve   SS Reserve
-----
vs1         vol1        ""         linux      45MB      45MB      45MB
```

Displays the maximum size of a LUN for the OS type linux.

```
cluster1::> lun maxsize -vserver vs1 -volume vol1
Vserver     Volume      Qtree      OS Type    Without    With SS    Complete
            Volume      Qtree      OS Type    SS Reserve Reserve   SS Reserve
-----
vs1         vol1        ""         aix        178MB     178MB     178MB
            hpux        178MB     178MB     178MB
            hyper_v    172.6MB   172.6MB   172.6MB
            linux      178MB     178MB     178MB
            netware    178MB     178MB     178MB
            openvms    178MB     178MB     178MB
            solaris    178MB     178MB     178MB
            solaris_efi 178MB     178MB     178MB
            windows   172.6MB   172.6MB   172.6MB
            windows_2008
                172.6MB   172.6MB   172.6MB
            windows_gpt 172.6MB   172.6MB   172.6MB
            xen      178MB     178MB     178MB
12 entries were displayed.
```

Displays the maximum size of LUNs for all OS types on volume vol1.

## Related Links

- [lun resize](#)

# lun modify

## Modify a LUN

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command modifies LUN attributes. Because LUN modifications can result in data corruption or other problems, we recommend that you call Fujitsu support personnel if you are unsure of the possible consequences of modifying a LUN.

## Parameters

### **-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver.

### **{ -path <path> - LUN Path**

Specifies the path for the LUN you want to modify. Examples of correct LUN paths are **/vol/vol1/lun1** and **/vol/vol1/qtrees1/lun1**.

### **| -volume <volume name> - Volume Name**

Specifies the volume for the LUN you want to modify.

### **-qtree <qtree name> - Qtree Name**

Specifies the qtree for the LUN you want to modify.

### **-lun <text> - LUN Name }**

Specifies the name for the LUN you want to modify. A LUN name is a case-sensitive name and has the following requirements:

- Must contain one to 255 characters. Spaces are not allowed.
- Can contain the letters A through Z, a through z, numbers 0 through 9, hyphen (-), underscore (\_), right bracket (}), left bracket ({) and period (.).
- Must start with a letter or number.

### **[-space-reserve {enabled|disabled}] - Space Reservation**

Specifies whether the space reservation setting is enabled or disabled for a LUN. If you set the parameter to **enabled**, the LUN is space-reserved. If you set the parameter to **disabled**, the LUN is non-space reserved. The default is **enabled**.

### **{ [-serial <text>] - Serial Number**

Specifies the serial number for the LUN you want to modify.

The LUN serial number is a twelve-character alphanumeric string containing one or more of the

following:

- upper- and lower-case letters
- numbers
- the characters: , < , > , / , - , # , \$ , % , \* , + , = , ? , @ , [ , ! , ] , ^ , ~

Some of the characters that are valid in a LUN serial number also have special meaning to the cluster shell command line:

- The question mark (?) activates the command line active help. In order to type a question mark as part of a LUN's serial number, it is necessary to disable active help with the command `set -active-help false`. Active help can later be re-enabled with the command `set -active-help true`.
- The number sign (#) indicates the beginning of a comment to the command line and will cause the remainder of the line to be ignored. To avoid this, enclose the serial number in double quotes (").

Alternatively, the `-serial-hex` parameter can be used to set the LUN serial number specifying the serial number encoded in hexadecimal form.

#### **[`-serial-hex <Hex String>`] - Serial Number (Hex) }**

Specifies the serial number, encoded in hexadecimal form, for the LUN you want to modify. See the description of the `-serial` parameter for additional details.

#### **[`-comment <text>`] - Comment**

Specifies the comment for the LUN you want to modify.

#### **[`-space-allocation {enabled|disabled}`] - Space Allocation**

Specifies the new value for the space allocation attribute of the LUN. The space allocation attribute determines if the LUN supports the SCSI Thin Provisioning features defined in the Logical Block Provisioning section of the SCSI SBC-3 standard.

Specifying **enabled** for this parameter enables support for the SCSI Thin Provisioning features.

Specifying **disabled** for this parameter disables support for the SCSI Thin Provisioning features.

Hosts and file systems that do not support SCSI Thin Provisioning should not enable space allocation.

#### **[`-state {online|offline|nvfail|space-error|foreign-lun-error}`] - State**

Specifies the administrative state of a LUN. The options are:

- online
- offline

#### **{ [`-device-legacy-id <integer>`] - Device Legacy ID**

Specifies the device legacy ID for the LUN you want to modify.

**[ [-device-binary-id <text>] - Device Binary ID**

Specifies the device binary ID for the LUN you want to modify.

**[ [-clear-binary-id <>true>] - Clear Device Binary ID }**

Clears the binary format of the optional device ID.

**{ [-device-text-id <text>] - Device Text ID**

Specifies the device text ID for the LUN you want to modify.

**[ [-clear-text-id <>true>] - Clear Device Text ID }**

Clears the text format of the optional device ID.

**{ [-qos-policy-group <text>] - QoS Policy Group**

This optionally specifies which QoS policy group to apply to the lun. This policy group defines measurable service level objectives (SLOs) that apply to the storage objects with which the policy group is associated. If you do not assign a policy group to a lun, the system will not monitor and control the traffic to it. To remove this lun from a policy group, enter the reserved keyword "none".

**[ [-qos-adaptive-policy-group <text>] - QoS Adaptive Policy Group }**

This optional parameter specifies which QoS adaptive policy group to apply to the LUN. This policy group defines measurable service level objectives (SLOs) and Service Level Agreements (SLAs) that adjust based on the LUN's allocated space or used space. To remove this LUN from an adaptive policy group, enter the reserved keyword "none".

**[-caching-policy <text>] - Caching Policy Name**

This optionally specifies the caching policy to apply to the LUN. A caching policy defines how the system caches this volume's data in Flash Cache modules. If a caching policy is not assigned to this LUN, the system uses the caching policy that is assigned to the containing volume or Vserver. If a caching policy is not assigned to the containing volume or Vserver, the system uses the default cluster-wide policy. The available caching policies are:

- none - Does not cache any user data or metadata blocks.
- auto - Read caches all metadata and randomly read user data blocks, and write caches all randomly overwritten user data blocks.
- meta - Read caches only metadata blocks.
- random\_read - Read caches all metadata and randomly read user data blocks.
- random\_read\_write - Read caches all metadata, randomly read and randomly written user data blocks.
- all\_read - Read caches all metadata, randomly read and sequentially read user data blocks.
- all\_read\_random\_write - Read caches all metadata, randomly read, sequentially read, and randomly written user data.
- all - Read caches all data blocks read and written. It does not do any write caching.

Default caching-policy is auto.

## Examples

```
cluster1::> lun modify -path /vol/vol1/lun1 -space-reserve disable
```

Disables the space reserve attribute for LUN /vol/vol1/lun1.

```
cluster1::> lun modify -path /vol/vol1/lun1 -state offline
```

Takes the LUN /vol/vol1/lun1 offline.

```
cluster1::> lun modify -path /vol/vol1/lun1 -comment "new comment"
```

Adds the comment "new comment" to the LUN /vol/vol1/lun1.

## Related Links

- [set](#)

# lun move-in-volume

Move a LUN within a volume

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command moves a LUN to a new path in the same volume or renames a LUN. If you are organizing LUNs in a qtree, the command moves a LUN from one qtree to another. You can perform a LUN move while the LUN is online and serving data. The process is non-disruptive. Use the [lun move start](#) command to move a LUN to a different volume within the same Vserver.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver.

**{ -path <path> - LUN Path**

Specifies the path of the LUN you want to move. Examples of correct LUN paths are **/vol/vol1/lun1** and **/vol/vol1/qtree1/lun1**.

**| -volume <volume name> - Volume Name**

Specifies the volume of the LUN you want to move.

**[-qtree <qtree name>] - Qtree Name**

Specifies the qtree of the LUN you want to move.

**-lun <text> - LUN Name }**

Specifies the name of the LUN that you want to move.

**{ -new-path <path> - New LUN Path**

Specifies the new path of the LUN. Examples of correct LUN paths are **/vol/vol1/lun1** and **/vol/vol1/qtree1/lun1**.

**| [-new-qtree <qtree name>] - New Qtree Name**

Specifies the new qtree name that you want to move the LUN to.

**-new-lun <text> - New LUN Name }**

Specifies the new name of the LUN.

## Examples

```
cluster1::> lun move-in-volume -vserver vs1 -volume vol1 -lun lun1 -new-lun newlun1
```

Renames **lun1** to **newlun1** on Vserver **vs1** and volume **vol1**.

```
cluster1::> lun show -vserver vs1 -volume vol1
server  Path                               State  Mapped  Type      Size
-----
s1      /vol/vol1/A/lun1                     online mapped  linux     10MB

cluster1::> lun move-in-volume -vserver vs1 -path /vol/vol1/A/lun1 -new-path
/vol/vol1/B/lun1

cluster1::> lun show -vserver vs1 -volume vol1
server  Path                               State  Mapped  Type      Size
-----
s1      /vol/vol1/B/lun1                     online mapped  linux     10MB
```

Moves LUN **lun1** from qtree **A** to qtree **B** on volume **vol1**.

## Related Links

- [lun move start](#)

# lun resize

Changes the size of the LUN to the input value size.

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command resizes an existing LUN.

If the value specified by the **-size** parameter is larger than the current size of the LUN, the LUN size will be increased to at least the requested size by appending new empty blocks to the end of the LUN. After resizing, follow the procedures provided by your host operating system to discover the new size of the LUN and expand the filesystem on the LUN.

If the value specified by the **-size** parameter is smaller than the current size of the LUN, the LUN size will be reduced to no less than the requested size by truncating blocks at the end of the LUN beyond the new size. All data in the truncated blocks will be lost. Prior to reducing the size of a LUN, you must follow the procedure provided by the host operating system to resize and migrate the filesystem on the LUN off the blocks that will be truncated. Not all operating systems and filesystems support shrinking an existing filesystem.

You will receive an error message warning of the potential for data loss if the command would reduce the size of the LUN. Once the host filesystem has been migrated off the blocks to be truncated, use the **-force** parameter to allow the resize to proceed.

Consider taking a Snapshot copy of the volume before reducing the size of the LUN. After the LUN has been resized and the contents verified, you may delete the Snapshot copy.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver.

**{ -path <path> - LUN Path**

Specifies the path of the LUN that you want to resize. Examples of correct LUN paths are **/vol/vol1/lun1** and **/vol/vol1/qtrees1/lun1**.

**| -volume <volume name> - Volume Name**

Specifies the volume that contains the LUN that you want to resize.

**[-mtree <mtree name>] - Mtree Name**

Specifies the mtree that contains the LUN that you want to resize.

**-lun <text> - LUN Name }**

Specifies the LUN name that you want to resize.

**[-f, -force <true>] - Force Reduce LUN Size**

Specifies the command may reduce the size of the specified LUN. If the specified **-size** is smaller than the existing size of the LUN and this parameter is not specified, the command will fail with an error instead of potentially destroying data. See the overall command description above for more information concerning reducing the size of a LUN.

**[-size <size>] - New Size**

Specifies the requested new size of the LUN. The actual size after resizing may be slightly larger than requested. If the value is prefixed with **+** or **-**, the new size will be calculated as the existing size plus or minus the value provided. The following multipliers are recognized as suffixes:

- B - Value specifies number of blocks (512 bytes)
- k - Value specifies number of kilobytes (1024 bytes)
- M - Value specifies number of megabytes (1024 kilobytes)
- G - Value specifies number of gigabytes (1024 megabytes)
- T - Value specifies number of terabytes (1024 gigabytes)

## Examples

```
cluster1::> lun resize -vserver vs1 -path /vol/vol1/lun1 -size 500M
```

Resizes the LUN /vol/vol1/lun1 in Vserver vs1 to 500 MB. If the LUN is already larger than 500 MB, this command will fail.

```
cluster1::> lun resize -vserver vs1 -path /vol/vol1/lun1 -size +50M
```

Adds 50 MB of space to LUN /vol/vol1/lun1

```
cluster1::> lun resize -vserver vs1 -path /vol/vol1/lun1 -size -10m
```

```
Error: command failed: Reducing LUN size without coordination with the host system  
may cause permanent data loss or corruption. Use the force flag to allow  
LUN size reduction.
```

```
cluster1::> lun resize -path /vol/vol1/lun1 -size -100M -force
```

Reduces the LUN /vol/vol1/lun1 by 100 MB.

# lun show

Display a list of LUNs

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The command displays information for LUNs. Use the **instance** parameter to display additional LUN details, such as serial number and space-reservation settings.

## Parameters

{ [-fields <fieldname>, ...]

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

| [-instance ]}

If you specify the **-instance** parameter, the command displays detailed information about all fields.

[-vserver <Vserver Name>] - Vserver Name

Selects the LUNs that match this parameter value.

{ [-path <path>] - LUN Path

Selects the LUNs that match this parameter value. Examples of correct LUN paths are **/vol/vol1/lun1** and **/vol/vol1/qtrees1/lun1**

| [-volume <volume name>] - Volume Name

Selects the LUNs that match this parameter value.

[-qtree <qtree name>] - Qtree Name

Selects the LUNs that match this parameter value.

[-lun <text>] - LUN Name }

Selects the LUNs that match this parameter value.

[-s, -size <size>] - LUN Size

Selects the LUNs that match this parameter value.

[-P, -prefix-size <size>] - Prefix Size

Selects the LUNs that match the prefix stream size that you specify.

[-t, -ostype <LUN Operating System Format>] - OS Type

Selects the LUNs that match this parameter value. The operating system types are:

- **aix** - the LUN stores AIX data.
- **hpux** - the LUN stores HP-UX data.
- **hyper\_v** - the LUN stores Windows Server 2008 or Windows Server 2012 Hyper-V data
- **linux** - the LUN stores a Linux raw disk without a partition table.
- **netware** - the LUN stores NetWare data.
- **openvms** - the LUN stores Open-VMS data
- **solaris** - the LUN stores Solaris raw disk in a single-slice partition.
- **solaris\_efi** - the LUN stores Solaris\_EFI data.
- **vmware** - the LUN stores VMware data
- **windows** - the LUN stores a raw disk type in a single-partition Windows disk using the Master Boot Record (MBR) partitioning style.
- **windows\_gpt** - the LUN stores Windows data using the GUID Partition Type (GPT) partitioning style.
- **windows\_2008** - the LUN stores Windows data for Windows 2008 or later systems.
- **xen** - the LUN stores Xen data

#### **[-space-reserve {enabled|disabled}] - Space Reservation**

Selects the LUNs that match this parameter value. A value of **enabled** selects LUN that are space-reserved. A value of **disabled** select LUNs that are non-space reserved.

#### **[-serial <text>] - Serial Number**

Selects the LUNs that match this parameter value.

The LUN serial number is a twelve-character alphanumeric string containing one or more of the following:

- upper- and lower-case letters
- numbers
- the characters: , <, >, /, -, #, \$, %, \*, +, =, ?, @, [ , ! ], ^, ~

Some of the characters that are valid in a LUN serial number also have special meaning to the cluster shell command:

- The question mark (?) activates the command line active help. In order to type a question mark as part of a LUN's serial number, it is necessary to disable active help with the command set -active-help false . Active help can later be re-enabled with the command set -active-help true .
- The number sign (#) indicates the beginning of a comment to the command line and will cause the remainder of the line to be ignored. To avoid this, enclose the serial number in double quotes (").
- The less than (<), greater than (>), asterisk (\*), and exclamation point (!) influence the query behavior of the command. To use these as characters in a LUN's serial query, you must first press escape (ESC). To use these characters to influence the query, enclose the serial number,

or partial serial number, in double quotes (") and apply <, >, \*, or !, outside of the double quotes.

Alternatively, the **-serial-hex** parameter can be used to select LUNs using the serial number encoded in hexadecimal form.

#### **[-serial-hex <Hex String>] - Serial Number (Hex)**

Selects the LUNs that match this parameter value. This parameter applies to the LUN serial number encoded in hexadecimal form. See the description of the **-serial** parameter for additional details.

#### **[-comment <text>] - Comment**

Selects the LUNs that match this parameter value.

#### **[-space-reserve-honored {true|false}] - Space Reservations Honored**

Selects the LUNs that match this parameter value. A value of **true** select LUNs that have their space reservation honored by the container volume. A value of **false** displays the LUNs that are non-space reserved.

#### **[-space-allocation {enabled|disabled}] - Space Allocation**

Selects the LUNs that match this parameter value. The space allocation attribute determines if the LUN supports the SCSI Thin Provisioning features defined in the Logical Block Provisioning section of the SCSI SBC-3 standard.

Specifying **enabled** for this parameter selects LUNs with support enabled for the SCSI Thin Provisioning features.

Specifying **disabled** for this parameter selects LUNs with support disabled for the SCSI Thin Provisioning features.

Hosts and file systems that do not support SCSI Thin Provisioning should not enable space allocation.

#### **[-container-state {online|aggregate-offline|volume-offline|error}] - LUN Container State**

Selects the LUNs that match this parameter value. The container states are:

- **online** - The LUN's aggregate and volume are online.
- **aggregate-offline** - The LUN's aggregate is offline.
- **volume-offline** - The LUN's volume is offline.
- **error** - An error occurred accessing the LUN's volume.

#### **[-state {online|offline|nvfail|space-error|foreign-lun-error}] - State**

Selects the LUNs that match this parameter value. The states are:

- **online** - The LUN is online.
- **offline** - The LUN is administratively offline, or a more detailed offline reason is not available.
- **foreign-lun-error** - The LUN has been automatically taken offline due to a media error on the associated foreign LUN.

- **nvfail** - The LUN has been automatically taken offline due to an NVRAM failure.
- **space-error** - The LUN has been automatically taken offline due to insufficient space.

**[-uuid <UUID>] - LUN UUID**

Selects the LUNs that match this parameter value.

**[-mapped {mapped|unmapped}] - Mapped**

Selects the LUNs that match this parameter value. A value of **mapped** selects the LUNs that are mapped to an initiator group.

**[-block-size {512|4KB}] - Physical Size of Logical Block**

Selects the LUNs that match this parameter value.

**[-device-legacy-id <integer>] - Device Legacy ID**

Selects the LUNs that match this parameter value.

**[-device-binary-id <text>] - Device Binary ID**

Selects the LUNs that match this parameter value.

**[-device-text-id <text>] - Device Text ID**

Selects the LUNs that match this parameter value.

**[-read-only {true|false}] - Read Only**

Selects the LUNs that match this parameter value.

**[-restore-inaccessible {true|false}] - Fenced Due to Restore**

Selects the LUNs that match the state you specify. A value of **true** means that a LUN is fenced for I/O and management due to a restore operation.

**[-size-used <size>] - Used Size**

Selects the LUNs that match this parameter value.

**[-max-resize-size <size>] - Maximum Resize Size**

Selects the LUNs that match this parameter value.

**[-creation-timestamp <MM/DD/YYYY HH:MM:SS>] - Creation Time**

Selects the LUNs that match this parameter value.

**[-class {regular|protocol-endpoint|vvol}] - Class**

Selects the LUNs that match this parameter value.

**[-node <nodename>] - Node Hosting the LUN**

Selects the LUNs that match this parameter value.

**[-qos-policy-group <text>] - QoS Policy Group**

Selects the LUNs that match this parameter value.

A policy group defines measurable service level objectives (SLOs) that apply to the storage

objects with which the policy group is associated. If you do not assign a policy group to a LUN, the system will not monitor and control the traffic to it.

### **[-qos-adaptive-policy-group <text>] - QoS Adaptive Policy Group**

Selects the LUNs that match this parameter value.

An adaptive policy group defines measurable service level objectives (SLOs) that apply to the storage objects with which the adaptive policy group is associated.

### **[-caching-policy <text>] - Caching Policy Name**

Display the LUNs that match the specified cache.

A caching policy defines the caching behavior of this LUN at the Flash Cache level. If a caching policy is not assigned to this LUN, the system uses the caching policy that is assigned to the containing volume or Vserver. If a caching policy is not assigned to the containing volume or Vserver, the system uses the default cluster-wide policy. The available caching policies are:

- none - Does not cache any user data or metadata blocks.
- auto - Read caches all metadata and randomly read user data blocks, and write caches all randomly overwritten user data blocks.
- meta - Read caches only metadata blocks.
- random\_read - Read caches all metadata and randomly read user data blocks.
- random\_read\_write - Read caches all metadata, randomly read and randomly written user data blocks.
- all\_read - Read caches all metadata, randomly read and sequentially read user data blocks.
- all\_read\_random\_write - Read caches all metadata, randomly read, sequentially read, and randomly written user data.
- all - Read caches all data blocks read and written. It does not do any write caching.

Default caching-policy is auto.

### **[-is-clone {true|false}] - Clone**

Selects the LUNs that match this parameter value.

### **[-is-clone-autodelete-enabled {true|false}] - Clone Autodelete Enabled**

Selects the LUNs that match this parameter value.

### **[-inconsistent-import {true|false}] - Inconsistent Import**

Selects the LUNs that match this parameter value. A value of **true** means that the import of this LUN is incomplete.

### **[-serial-7-mode <text>] - 7-mode Serial Number**

Selects the LUNs that match this parameter value.

LUNs transitioned from Data ONTAP 7-Mode are assigned new serial numbers for use with Clustered Data ONTAP. The original 7-Mode serial number is displayed in this field for reference.

**[-application <text>] - Application**

Selects the LUNs that are part of an application that matches the parameter value.

**[-include-offline-containers <true>] - Include LUNs on Offline Volumes and Aggregates**

If true, include available information for LUNs in offline aggregates and offline volumes in the output. By default, LUNs in offline aggregates and offline volumes are excluded from the output.

**[-zrto-vol-consensus {true|false}] - ZRTO Volume consensus**

Select the LUNs that match the specified value. The status indicates whether the volume containing the LUN in a Synchronous Snapmirror relationship can process operations.

## Examples

The following example displays details of the LUN at path /vol/vol1/lun1 in Vserver vs1.

```
cluster1::> lun show -vserver vs1 -path /vol/vol1/lun1 -instance
      Vserver Name: vs1
        LUN Path: /vol/vol1/lun1
      Volume Name: vol1
        Qtree Name: ""
        LUN Name: lun1
        LUN Size: 10MB
        OS Type: linux
      Space Reservation: disabled
        Serial Number: wCVt1]IlvQWv
      Serial Number (Hex): 77435674315d496c76515776
        Comment: new comment
      Space Reservations Honored: false
        Space Allocation: disabled
          State: offline
          LUN UUID: 76d2eba4-dd3f-494c-ad63-1995c1574753
          Mapped: mapped
          Block Size: 512
        Device Legacy ID: -
        Device Binary ID: -
        Device Text ID: -
          Read Only: false
      Fenced Due to Restore: false
        Used Size: 5MB
      Maximum Resize Size: 64.00GB
        Creation Time: 9/14/2016 13:55:09
          Class: regular
      Node Hosting the LUN: node1
        QoS Policy Group: -
      Caching Policy Name: -
        Clone: false
      Clone Autodelete Enabled: false
      Inconsistent Import: false
```

Application: -

The following example displays information for the LUN with serial number 1r/wc+9Cpbls:

```
cluster1::> lun show -serial 1r/wc+9Cpbls
Vserver  Path                               State  Mapped  Type      Size
-----  -
vs1      /vol/vol2/lun1                     online mapped  linux     10MB
```

The following example displays all the LUNs on Vserver vs1 and volume vol1:

```
cluster1::> lun show -vserver vs1 -volume vol1
Vserver  Path                               State  Mapped  Type      Size
-----  -
vs1      /vol/vol1/lun1                     offline mapped  linux     10MB
vs1      /vol/vol1/lun2                     online  mapped  windows   47.07MB
2 entries were displayed.
```

- [set](#)

# lun bind create

Bind a VVol LUN to a protocol endpoint

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

This command creates a new binding between a protocol endpoint and a vvol LUN. If a binding between the specified endpoint and vvol already exists, the reference count for the binding is incremented by one.

For optimal results, the protocol endpoint and vvol must be hosted by the same node in the cluster.

## Parameters

**-vserver <Vserver Name>** - Vserver name

Specifies the name of the Vserver.

**-protocol-endpoint-path <path> - Protocol Endpoint**

Specifies the path to the protocol endpoint. The specified LUN must already exist and be of class "protocol-endpoint". Examples of correct LUN paths are **/vol/vol1/lun1** and **/vol/vol1/qtrees1/lun1**.

**-vvol-path <path> - VVol Path**

Specifies the path to the vvol. The specified LUN must already exist and be of the class "vvol". Examples of correct LUN paths are **/vol/vol1/lun1** and **/vol/vol1/qtrees1/lun1**.

## Examples

```
cluster1::*> lun bind create -vserver vs1 -protocol-endpoint-path /vol/VV1/PE1 -vvol  
-path /vol/VV3/234ace
```

Bind the vvol **/vol/VV3/234ace** to the protocol endpoint **/vol/VV1/PE1** in Vserver **vs1**.

# lun bind destroy

Unbind a VVol LUN from a protocol endpoint

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

Decrement the reference count of the binding between a protocol endpoint and vvol LUN. If the resulting reference count is zero, the binding is removed.

## Parameters

**-vserver <Vserver Name> - Vserver name**

Specifies the Vserver.

**-protocol-endpoint-path <path> - Protocol Endpoint**

Specifies the path of the protocol endpoint LUN. Examples of correct LUN paths are **/vol/vol1/lun1** and **/vol/vol1/qtrees1/lun1**.

**-vvol-path <path> - VVol Path**

Specifies the path of the vvol LUN. Examples of correct LUN paths are **/vol/vol1/lun1** and **/vol/vol1/qtrees1/lun1**.

**[-force <true>] - If true, unbind the Vvol completely even if the current reference count is greater than 1. The default is false.**

Completely remove the specified binding, regardless of the current reference count.

## Examples

```
cluster1::*> lun bind destroy -protocol-endpoint-path /vol/VV2/PE2 -vvol-path  
/vol/VV2/30dfab -vserver vs1
```

Remove the binding between the vvol /vol/VV2/30dfab and the protocol endpoint /vol/VV2/PE2 on Vserver vs1.

## lun bind show

Show list of Vvol bindings

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

Shows the configured VVol to protocol endpoint bindings.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[ [-instance ] ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-vserver <Vserver Name>] - Vserver Name**

Selects the bindings that match this parameter value.

**[-protocol-endpoint-msid <integer>] - PE MSID**

Selects the bindings that match this parameter value.

**[-protocol-endpoint-vdisk-id <text>] - PE Vdisk ID**

Selects the bindings that match this parameter value.

**[-vvol-msid <integer>] - VVol MSID**

Selects the bindings that match this parameter value.

**[-vvol-vdisk-id <text>] - VVol Vdisk ID**

Selects the bindings that match this parameter value.

**[-vserver-uuid <UUID>] - Vserver UUID**

Selects the bindings that match this parameter value.

**[-protocol-endpoint-path <path>] - Protocol Endpoint**

Selects the bindings that match this parameter value. Examples of correct LUN paths are **/vol/vol1/lun1** and **/vol/vol1/qtrees1/lun1**.

**[-protocol-endpoint-node <nodename>] - PE Node**

Selects the bindings that match this parameter value.

**[-vvol-path <path>] - VVol**

Selects the bindings that match this parameter value. Examples of correct LUN paths are **/vol/vol1/lun1** and **/vol/vol1/qtrees1/lun1**.

**[-vvol-node <nodename>] - VVol Node**

Selects the bindings that match this parameter value.

**[-secondary-lun <Hex 64bit Integer>] - Secondary LUN**

Selects the bindings that match this parameter value.

**[-is-optimal {true|false}] - Optimal binding**

Selects the bindings that match this parameter value.

**[-reference-count <integer>] - Reference Count**

Selects the bindings that match this parameter value.

## Examples

```
cluster1::*> lun bind show -vserver vs1
Vserver          Protocol Endpoint          Node
                  Vvol LUN                    Secondary LUN Optimal?
-----
vs1              /vol/VV1/PE1              cluster-node1
                  /vol/VV2/30dfab          d20000010000 false
                  /vol/VV3/234ace          d20000020000 true
                  /vol/VV3/234acf          d20000030000 true
                  /vol/VV2/PE2              cluster-node2
                  /vol/VV2/30dfab          d20000010000 true
4 entries were displayed.
```

The example above displays all the LUN bindings on Vserver vs1.

## lun copy cancel

Cancel a LUN copy operation before the new LUN has been created

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

The **lun copy cancel** command cancels an ongoing LUN copy operation prior to creation of the new LUN. The command fails if the LUN already exists at the destination path; in that case, use the [lun delete](#) command to delete the LUN at the destination path.

All data transfers will be halted.

This is an advanced command because the preferred way to cancel a LUN copy operation is to wait until the new LUN becomes visible, and then use the [lun delete](#) command to delete the LUN.

## Parameters

**{ -vserver <Vserver Name> - Vserver Name**

Specifies the name of the Vserver that will host the destination LUN.

**-destination-path <path> - Destination Path**

Specifies the full path to the new LUN, in the format `/vol/<volume>[/<qtree>]/<lun>`.

## Examples

```
cluster1::*> lun copy cancel -vserver vs1 -destination-path /vol/vol2/lun2
```

Cancels the copy operation identified by Vserver **vs1** and destination path **/vol/vol2/lun2**.

## Related Links

- [lun delete](#)

# lun copy modify

Modify an ongoing LUN copy operation

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **lun copy modify** command modifies the maximum throughput of an ongoing copy operation.

## Parameters

{ **-vserver <Vserver Name> - Vserver Name**

Specifies the name of the Vserver that will host the destination LUN.

**-destination-path <path> - Destination Path**

Specifies the full path to the new LUN, in the format /vol/<volume>[/<qtree>]/<lun>.

**-max-throughput {<integer>[KB|MB|GB|TB|PB]} - Maximum Transfer Rate (per sec)**

Specifies the maximum amount of data, in bytes, that can be transferred per second in support of this operation. This mechanism can be used to throttle a transfer, to reduce its impact on the performance of the source and destination nodes.

The specified value will be rounded up to the nearest megabyte.

## Examples

```
cluster1::> lun copy modify -vserver vs1 -destination-path /vol/vol2/lun2 -max  
-throughput 25MB
```

Modifies the maximum throughput for the ongoing copy job identified by Vserver **vs1** and destination path **/vol/vol2/lun2** to 25 MB/sec.

# lun copy pause

Pause an ongoing LUN copy operation

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **lun copy pause** command pauses an ongoing copy operation. Use the [lun copy resume](#) command to resume the copy operation.

## Parameters

{ **-vserver <Vserver Name> - Vserver Name**

Specifies the name of the Vserver that will host the destination LUN.

**-destination-path <path> - Destination Path**

Specifies the full path to the new LUN, in the format /vol/<volume>[/<qtree>]/<lun>.

## Examples

```
cluster1::> lun copy pause -vserver vs1 -destination-path /vol/vol2/lun2
```

Pauses the ongoing copy operation identified by Vserver **vs1** and destination path **/vol/vol2/lun2** .

## Related Links

- [lun copy resume](#)

# lun copy resume

Resume a paused LUN copy operation

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **lun copy resume** command resumes a paused copy operation.

## Parameters

{ **-vserver** <Vserver Name> - **Vserver Name**

Specifies the name of the Vserver that will host the destination LUN.

**-destination-path** <path> - **Destination Path**

Specifies the full path to the new LUN, in the format `/vol/<volume>[/<qtree>]/<lun>`.

## Examples

```
cluster1::> lun copy resume -vserver vs1 -destination-path /vol/vol2/lun2
```

Resumes the paused copy operation identified by Vserver **vs1** and destination path **/vol/vol2/lun2** .

# lun copy show

Display a list of LUNs currently being copied

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `lun copy show` command shows information about LUNs currently being copied in the cluster.

## Parameters

`{ [-fields <fieldname>, ... ] }`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

`[ [-instance ] ] }`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-vserver <Vserver Name>] - Destination Vserver Name`

Selects LUN copy operations that match this parameter value.

`[-destination-path <path>] - Destination Path`

Selects LUN copy operations that match this parameter value.

`[-source-vserver <vserver name>] - Source Vserver Name`

Selects LUN copy operations that match this parameter value.

`[-source-path <path>] - Source Path`

Selects LUN copy operations that match this parameter value.

`[-source-snapshot <snapshot name>] - Source Snapshot Name`

Selects LUN copy operations that match this parameter value.

`[-is-promoted-early {true|false}] - Is Destination Promoted Early`

Selects LUN copy operations that match this parameter value.

`[-max-throughput {<integer>[KB|MB|GB|TB|PB]}] - Maximum Transfer Rate (per sec)`

Selects LUN copy operations that match this parameter value.

`[-job-status {Preparing|Allocation-Map|Data|Destroying|Paused-Manual|Paused-Error|Complete|Destroyed|Terminated-Manual}] - LUN Copy Status`

Selects LUN copy operations that match this parameter value. The possible values are:

- **Preparing** - the LUN copy job is in Preparing status.
- **Allocation-Map** - the LUN copy job is in Allocating status.
- **Data** - the LUN copy job is in Moving Data status.
- **Destroying** - the LUN copy job is in Destroying status.
- **Paused-Manual** - the LUN copy job is in Manually Paused status.
- **Paused-Error** - the LUN copy job is in Paused By Error status.

- **Complete** - the LUN copy job is in Complete status.
- **Destroyed** - the LUN copy job is in Destroyed status.
- **Terminated-Manual** - the LUN copy job is in Manually Terminated status.

**[-progress-percent <percent>] - LUN Copy Progress (%)**

Selects LUN copy operations that match this parameter value.

**[-elapsed-time <time\_interval>] - Elapsed Time**

Selects LUN copy operations that match this parameter value.

**[-cutover-time <time\_interval>] - Cutover Time**

Selects LUN copy operations that match this parameter value.

**[-is-snapshot-fenced {true|false}] - Is Snapshot Fenced**

Selects LUN copy operations that match this parameter value.

**[-is-destination-ready {true|false}] - Is Destination Ready**

Selects LUN copy operations that match this parameter value.

**[-last-failure-reason <text>] - Last Failure Reason**

Selects LUN copy operations that match this parameter value.

## Examples

```
cluster1::> lun copy show
Vserver      Destination Path          Status      Progress
-----
vs1          /vol/vol2/lun1          Data        35%
vs1          /vol/vol2/lun2          Complete    100%
2 entries were displayed.
```

The example above displays information about all the LUN copy operations in the cluster.

```
cluster1::> lun copy show -vserver vs1 -destination-path /vol/vol2/lun1 -instance
Destination Vserver Name: vs1
      Destination Path: /vol/vol2/lun1
      Source Vserver Name: vs1
      Source Path: /vol/vol1/lun1
      Source Snapshot Name: -
      Is Destination Promoted Early: false
Maximum Transfer Rate (per sec): 0B
      LUN Copy Status: Data
      LUN Copy Progress (%): 35%
      Elapsed Time: 145s
      Cutover Time (secs): 0s
      Is Snapshot Fenced: true
      Is Destination Ready: true
```

Last Failure Reason: -

The example above displays all information about the LUN being copied to **/vol/vol2/lun1** in Vserver **vs1**.

## lun copy start

Start copying a LUN from one volume to another within a cluster

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **lun copy start** command initiates copying of a LUN from one volume to another. The destination volume can be located in the same Vserver as the source volume (intra-Vserver copy) or in a different Vserver (inter-Vserver).

A cluster administrator must first create a Vserver peering relationship using [vserver peer create](#) before initiating an inter-Vserver LUN copy operation.

## Parameters

**-vserver <Vserver Name> - Destination Vserver Name**

Specifies the name of the Vserver that will host the new LUN.

**[-destination-path <path> - Destination Path**

Specifies the full path to the new LUN, in the format `/vol/<volume>[/<qtree>]/<lun>`.

**-source-path <path> - Source Path }**

Specifies the full path to the source LUN, in the format `/vol/<volume>[/<snapshot/<snapshot>][/<qtree>]/<lun>`.

**[-source-vserver <vserver name>] - Source Vserver Name**

Optionally specifies the name of the Vserver hosting the LUN to be copied.

If this parameter is not specified, it is assumed that an intra-Vserver copy operation is being initiated. The source volume is expected to be in the same Vserver as the destination volume.

**[-promote-early <true>] - Promote Early**

Optionally specifies that the destination LUN needs to be promoted early.

If the destination is promoted early, the new LUN will be visible immediately. However, Snapshot copies of the volume containing the new LUN cannot be taken until the LUN copy operation reaches 'Moving Data' status.

If the destination is promoted late, the new LUN will be visible only after it has been fully framed. However, the LUN copy job will not block the creation of Snapshot copies of the volume containing the new LUN.

If this parameter is not specified, the destination LUN will be promoted late.

### **[-max-throughput {<integer>[KB|MB|GB|TB|PB]}] - Maximum Transfer Rate (per sec)**

Optionally specifies the maximum amount of data, in bytes, that can be transferred per second in support of this operation. This mechanism can be used to throttle a transfer, to reduce its impact on the performance of the source and destination nodes.

If this parameter is not specified, throttling is not applied to the data transfer.

The specified value will be rounded up to the nearest megabyte.

## Examples

```
cluster1::> lun copy start -vserver vs2 -destination-path /vol/vol2/lun2 -source  
-vserver vs1 -source-path /vol/vol1/lun1
```

Starts an inter-Vserver copy of LUN **lun1** from volume **vol1** in Vserver **vs1** to **lun2** on volume **vol2** in Vserver **vs2** .

```
cluster1::> lun copy start -vserver vs1 -destination-path /vol/vol2/lun2 -source-path  
/vol/vol1/lun1
```

Starts an intra-Vserver copy of LUN **lun1** from volume **vol1** in Vserver **vs1** to **lun2** on volume **vol2** in Vserver **vs1** .

```
cluster1::> lun copy start -vserver vs1 -destination-path /vol/vol2/lun2 -source-path  
/vol/vol1/.snapshot/snap1/lun1
```

Starts an intra-Vserver copy of LUN **lun1** from Snapshot copy **snap1** of volume **vol1** in Vserver **vs1** to **lun2** on volume **vol2** in Vserver **vs1** .

## Related Links

- [vserver peer create](#)

# lun igroup add

Add initiators to an initiator group

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege

level.

## Description

This command adds initiators to an existing initiator group (igroup). You can add an initiator to an initiator group only if there are no LUN mapping conflicts. Mapping conflicts occur when an initiator is already paired with a LUN. If you attempt to run this command and there are LUN mapping conflicts, the command returns an error.

An initiator cannot be a member of two igroups of different OS types. For example, if you have an initiator that belongs to a Solaris igroup, the command does not allow you to add this initiator to an AIX igroup.

When you add FCP initiators, you can specify an alias instead of the initiator's World Wide Port Name (WWPN) or the iSCSI Qualified name (IQN).

## Parameters

**-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver.

**-igroup <text> - Igroup Name**

Specifies the initiator group to which you want to add a new initiator.

**[-initiator <text>,...] - Initiators**

Specifies the initiator that you want to add. You can specify the WWPN, IQN, or alias of the initiator.

**[-child-igroups <text>,...] - Child Igroups**

Specifies the child initiator groups you want to add. The initiator group inherits the initiators of any child igroups. An initiator group can have either initiators or child initiator groups, but not both simultaneously. Initiator groups can be nested to match host cluster hierarchies. If the host cluster then changes, initiators only need to be updated in the child igroups and the parent igroups inherit the changes.

## Examples

```
cluster1::> lun igroup add -vserver vs1 -igroup ig1 -initiator iqn.1992-08.com.mv.mvinitiator
```

Adds the initiator `iqn.1992-08.com.mv.mvinitiator` to the initiator group `ig1` on Vserver `vs1`.

## lun igroup bind

Bind an existing initiator group to a given portset

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command binds an initiator group to a portset so the host knows which LIFs or TPGs to access. When you bind a portset to an igroup, the host knows which iSCSI or FCP LIF to access. If you do not bind an igroup to a portset, and you map a LUN to the igroup, then the initiators in the igroup can access the LUN on any port on the Vserver.

The initiator group cannot be bound to another portset when you use this command. If you attempt to bind a portset to an initiator group that is already bound to an existing portset, the command returns an error. You can only bind an initiator group to one portset at a time.

If the initiator group is bound, use the [lun igroup unbind](#) command to unbind the initiator group from the portset. After the initiator group is unbound, you can bind it to another portset.

You can only bind an initiator group to a non-empty portset.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver.

**-igroup <text> - Igroup Name**

Specifies the initiator group that you want to bind a portset to.

**-portset <text> - Portset Binding Igroup**

Specifies the portset name that you want to bind an initiator group to.

## Examples

```
cluster1::> lun igroup bind -vserver vs1 -igroup ig1 -portset-name ps1
```

Binds igroup ig1 to portset ps1.

## Related Links

- [lun igroup unbind](#)

# lun igroup create

Create a new initiator group

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege

level.

## Description

This command creates a new initiator group (igroup). Use igroups to control which hosts have access to specific LUNs. When you bind an igroup to a portset, a host in the igroup can access the LUNs only by connecting to the target ports in the portset.

When you create an igroup, you can add multiple existing initiators by specifying them in a list, separating them with commas. Later, you can add or remove initiators from the initiator group. Use the [lun igroup add](#) command to add initiators. Use the [lun igroup remove](#) command to remove an initiator. Unless the **-initiator** option is supplied, no initiators are added to a new igroup.

You can also bind a portset to an initiator when you create an initiator group. You can modify the portset binding of an initiator group by using the [lun igroup bind](#) command or the [lun igroup unbind](#) command.

The name you assign to an igroup is independent of the name of the host that is used by the host operating system, host files, or Domain Name Service (DNS). If you name an igroup aix1, for example, it is not mapped to the actual IP host name (DNS name) of the host.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver.

**-igroup <text> - Igroup Name**

Specifies the name of the new initiator group. An initiator group name is a case-sensitive name that must contain one to 96 characters. Spaces are not allowed.

It might be useful to provide meaningful names for igroups, ones that describe the hosts that can access the LUNs mapped to them.

**{ [-protocol {mixed|fcp|iscsi}] - Protocol**

Specifies if the initiator group protocol is **fcp**, **iscsi**, or **mixed**.

**[-f, -fcp <>true>] - FCP**

Specifies FCP as the protocol type of the new igroup.

**[-i, -iscsi <>true>] - iSCSI }**

Specifies iSCSI as the protocol type of the new igroup.

**-t, -ostype <Initiator Group OS Type> - OS Type**

Specifies the operating system type for the new initiator group. The operating system type indicates the type of host operating system used by all of the initiators in the igroup. All initiators in an igroup must be of the same operating system type. The operating system types of initiators are

- solaris
- windows
- hpux
- aix
- linux
- netware
- vmware
- openvms
- xen
- hyper\_v

#### **[-a, -portset <text>] - Portset Binding Igroup**

Specifies that a portset is bound to the initiator.

#### **{ -initiator <text>,... - Initiators**

Specifies the initiators that are attached to the new initiator group. By default, no initiators are added to the new igroup.

#### **[ -child-igroups <text>,... ] - Child Igroups }**

Specifies the child initiator groups that are attached to the new initiator group. The initiator group inherits the initiators of any child igroups. An initiator group can have either initiators or child initiator groups, but not both. Initiator groups can be nested to match host cluster hierarchies. If the host cluster then changes, initiators only need to be updated in the child igroups and the parent igroups inherit the changes.

#### **[-delete-on-unmap {true|false}] - Delete on Last Unmap**

Specifies if this initiator group will be deleted automatically when no longer a member of a LUN mapping relationship.

#### **[-comment <text>] - Igroup Comment**

A description for the igroup to create. If the comment string contains white space, it must be enclosed in double quotes. The limit is 254 characters.

## Examples

```
cluster1::> lun igroup create -vserver vs1 -igroup ig1 -protocol mixed -ostype linux
-initiator iqn.2001-04.com.example:abc123
```

Creates initiator group **ig1** on Vserver **vs1** with a **mixed** protocol type on a Linux operating system with the initiator **iqn.2001-04.com.example:abc123**.

## Related Links

- [lun igroup add](#)
- [lun igroup remove](#)
- [lun igroup bind](#)
- [lun igroup unbind](#)

# lun igroup delete

Delete an initiator group

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command deletes an existing initiator group. By default, you cannot delete an initiator group if LUN maps for that initiator group exist. You need to unmap all the LUNs that are associated with that initiator group before you can delete the initiator group. Use the [lun unmap](#) command to remove LUNS from an initiator group.

You can specify the **force** option to delete an initiator group and remove existing LUN maps defined for that initiator group.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver.

**-igroup <text> - Igroup Name**

Specifies the initiator group that you want to delete.

**[-f, -force <>true>] - Force**

Deletes an initiator group and all associated LUN maps.

## Examples

```
cluster1::> lun igroup delete -vserver vs1 -igroup ig1
```

Deletes the initiator group ig1 on Vserver vs1.

## Related Links

- [lun unmap](#)

# lun igroup disable-aix-support

Disables SAN AIX support on the cluster

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

This command disables the SAN AIX support across the cluster (all Vservers and all AIX initiator groups). However, before you can disable SAN AIX support, you must remove all SAN AIX related objects from the cluster. You need to unmap all the LUNs that are associated with the AIX initiator groups. Then you need to delete all of the AIX initiator groups. Use the [lun unmap](#) command to remove LUNS from an initiator group. Use the **igroup delete** command to delete an initiator group.

This command is not intended to be used in normal operation. Use only when you are downgrading to a release that does not support SAN AIX operation.

## Examples

```
cluster1::> lun igroup disable-aix-support
```

Disables the SAN AIX support for cluster1.

## Related Links

- [lun unmap](#)

# lun igroup modify

Modify an existing initiator group

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command modifies an attribute for an initiator group. Currently, the only settable attribute is the operating system.

## Parameters

### **-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver.

### **-igroup <text> - Igroup Name**

Specifies the initiator group whose attribute you want to modify.

### **[-t, -ostype <Initiator Group OS Type>] - OS Type**

Specifies the operating system that you want to modify. The operating system types of initiators are

- solaris
- windows
- hpux
- aix
- linux
- netware
- vmware
- openvms
- xen
- hyper\_v

### **[-delete-on-unmap {true|false}] - Delete on Last Unmap**

Specifies if this initiator group will be deleted automatically when no longer a member of a LUN mapping relationship.

### **[-comment <text>] - Igroup Comment**

Specifies the comment for the igroup you want to modify. If the comment string contains white space, it must be enclosed in double quotes. The limit is 254 characters. To clear the comment, specify the empty string enclosed in double quotes.

## Examples

```
cluster1::> lun igroup modify -vserver vs1 -igroup ig1 -ostype windows
```

Changes the operating system to **windows** for initiator group **ig1** on Vserver **vs1**.

## lun igroup remove

Remove initiators from an initiator group

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command removes an initiator from an initiator group. You can only remove an initiator if no existing LUN maps are defined for that initiator group. You must unmap the LUNs from the initiator group with the [lun unmap](#) command before you can remove initiators from the initiator group.

You can use the **force** option to remove an initiator and associated LUN maps.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver.

**-igroup <text> - Igroup Name**

Specifies the initiator group from which to remove an initiator.

**[-initiator <text>,...] - Initiators**

Specifies the initiator name to remove. Use the WWPN, IQN or the alias of the initiator.

**[-f, -force <>true>] - Force**

Forcibly removes an initiator and any associated LUN maps.

**[-child-igroups <text>,...] - Child Igroups**

Specifies the child initiator groups to remove.

## Examples

```
cluster1::> lun igroup remove -vserver vs1 -igroup ig1 -initiator iqn.1992-08.com.mv.mvinitiator
```

Removes the initiator `iqn.1992-08.com.mv.mvinitiator` from Vserver `vs1` and initiator group `ig1`.

## Related Links

- [lun unmap](#)

# lun igroup rename

Rename an existing initiator group

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command renames an existing initiator group. When you rename an initiator group, this action does not affect access to the LUNs mapped to the initiator group you want to rename.

An initiator group name is a case-sensitive name and must meet the following requirements:

- Must contain one to 96 characters. Spaces are not allowed.
- Can contain the letters A through Z, a through z, numbers 0 through 9, hyphen (-), underscore (\_), colon (:), and period (.).
- Must start with a letter or number.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver.

**-igroup <text> - Igroup Name**

Specifies the initiator group you want to rename.

**-new-name <text> - New Igroup Name**

Specifies the new name of the initiator group.

## Examples

```
cluster1::> lun igroup rename -vserver vs1 -igroup ig1 -new-name ignew1
```

Renames an initiator group from ig1 to ignew1 on Vserver vs1.

## lun igroup show

Display a list of initiator groups

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command displays status information for initiator groups (igroup). By default, the command displays status for all initiator groups.

## Parameters

### {[-fields <fieldname>,...]}

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

### [-instance ]}

If you specify the **-instance** parameter, the command displays detailed information about all fields.

### [-vserver <Vserver Name>] - Vserver Name

Specifies the Vserver.

### [-igroup <text>] - Igroup Name

Selects the initiator groups that match this parameter value.

### [-protocol {mixed|fcp|iscsi}] - Protocol

Selects the initiator groups that match this parameter value (**FCP** , **iSCSI** , or **mixed** ).

### [-t, -ostype <Initiator Group OS Type>] - OS Type

Selects the initiator groups that match this parameter value. The operating system types are

- solaris
- windows
- hpux
- aix
- linux
- netware
- vmware
- openvms
- xen
- hyper\_v

### [-a, -portset <text>] - Portset Binding Igroup

Selects the initiator groups that match this parameter value.

### [-initiator <text>,...] - Initiators

Selects the initiator groups that match this parameter value.

### [-child-igroups <text>,...] - Child Igroups

Selects the initiator groups that match this parameter value.

### [-uuid <UUID>] - Igroup UUID

Selects the initiator groups that match this parameter value.

**[-delete-on-unmap {true|false}] - Delete on Last Unmap**

Selects the initiator groups that match this parameter value. A value of **true** displays all the initiator groups that will be deleted automatically when they are no longer used in a LUN mapping relationship.

**[-comment <text>] - Igroup Comment**

Selects the igroups that match this parameter value.

## Examples

```
cluster1::> igroup show -instance
      Vserver Name: vs0
      Igroup Name: ig1
      Protocol: mixed
      OS Type: linux
Portset Binding Igroup: -
      Igroup UUID: 358338ba-cfd6-11df-a9ab-123478563412
      Initiators: iqn.1992-08.com.mv:abc (not logged in)
Vserver Name: vs0
      Igroup Name: ig2
      Protocol: mixed
      OS Type: linux
Portset Binding Igroup: -
      Igroup UUID: 3fb136c7-cfd6-11df-a9ab-123478563412
      Initiators: -
Vserver Name: vs1
      Igroup Name: ig1
      Protocol: mixed
      OS Type: windows
Portset Binding Igroup: p1
      Igroup UUID: 03accf6b-d08c-11df-a9ab-123478563412
      Initiators: -
3 entries were displayed.
```

The example above displays information about all initiator groups.

# lun igroup unbind

Unbind an existing initiator group from a portset

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command unbinds an initiator group from a portset. When you unbind an initiator group from a

portset, all of the initiators in the initiator group have access to all target LUNs on all network interfaces.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver.

**-igroup <text> - Igroup Name**

Specifies the initiator group that you want to unbind from the portset.

## Examples

```
cluster1::> lun igroup unbind -vserver vs1 -igroup ig1
```

Unbinds the initiator group ig1 from the portset on Vserver vs1.

# lun igroup initiator modify

Modify an initiator

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command modifies an attribute for an initiator.

## Parameters

**-vserver <Vserver Name> - Vserver**

Specifies the vservers of the initiator you want to modify.

**-initiator <text> - Initiator**

Specifies the initiator whose attribute you want to modify.

**[-comment <text>] - Comment**

The initiator's new comment. The comment has a maximum length of 255 characters. To clear the current comment, provide an empty string.

## Examples

```
cluster1::> lun igroup initiator modify -vserver vs1 -initiator iqn.1991-
```

```
05.com.example:name -comment "My application host"
```

Changes the comment to "My application host" for initiator **iqn.1991-05.com.example:name** in Vserver **vs1**.

```
cluster1::> lun igroup initiator modify -vserver vs1 -initiator iqn.1991-05.com.example:name -comment ""
```

Clears the comment for initiator **iqn.1991-05.com.example:name** in Vserver **vs1**.

## lun igroup initiator show

Display initiators

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

### Description

This command displays information for initiators that are members of initiator groups (igroups).

### Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[ -vserver <Vserver Name> ] - Vserver**

Selects the initiators of igroups whose Vserver matches the specified value.

**[ -initiator <text> ] - Initiator**

Selects initiators whose name matches the specified value.

**[ -comment <text> ] - Comment**

Selects initiators whose comment matches the specified value.

**[ -igroups <text>, ... ] - Igroups**

Selects initiators belonging to the specified igroups.

## Examples

```
cluster1::> lun igroup initiator show -instance
  Vserver: vs0
Initiator: init1
  Comment: Initiator Comment
  Igroups: ig1,ig2
Vserver: vs0
Initiator: init2
  Comment: Initiator Comment2
  Igroups: ig3
2 entries were displayed.
```

This example displays detailed information for all initiators in igroups.

## lun import create

Create an import relationship

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

This command creates an import relationship between a specified LUN and a specified foreign disk so you can import the foreign disk data into a LUN.

The foreign disk must be marked as foreign using [storage disk set-foreign-lun](#) command before you can begin the import progress.

The LUN must be of the same size as the foreign disk.

### Parameters

**-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver that contains the LUN where you import data to from the foreign disk data.

**-foreign-disk <text> - Foreign Disk Serial Number**

Specifies the serial number of the Foreign Disk.

**-path <path> - LUN Path**

Specifies the path of the LUN where you want to import the data of the foreign disk to. Examples of correct LUN paths are **/vol/vol1/lun1** and **/vol/vol1/qtrees1/lun1**.

## Examples

```
cluster1::> lun import create -vserver vs1 -path /vol/dvol1/lun1 -foreign-disk
6000B5D0006A0000006A020E00040000
```

Creates an import relationship between lun1 at the path /vol/dvol1/lun1 and foreign disk with serial number 6000B5D0006A0000006A020E00040000.

## Related Links

- [storage disk set-foreign-lun](#)

# lun import delete

Deletes the import relationship of the specified LUN or the specified foreign disk

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command deletes the import relationship of a specified LUN or a specified foreign disk.

You cannot use this command if an import is in-progress between the foreign disk and the LUN unless you use the force option. The import has to either successfully completed or be stopped before deleting the import relationship.

You can use the [lun import stop](#) command to stop the data import, and then you delete the import relationship.

## Parameters

**{ -vserver <Vserver Name> - Vserver Name**

Specifies the Vserver that contains the LUN that you want to delete the import relationship.

**-path <path> - LUN Path**

Specifies the path of the LUN where you want to delete the import relationship. Examples of correct LUN paths are **/vol/vol1/lun1** and **/vol/vol1/qtrees1/lun1**.

**[ -foreign-disk <text> - Foreign Disk Serial Number ]**

Specifies the serial number of the foreign disk.

**[-force {true|false}] - Force Delete**

When set to true, stops the in progress data import.

## Examples

```
cluster1::> lun import delete -vserver vs1 -path /vol/vol2/lun2
```

Deletes the import relationship of lun2 at the path /vol/vol2/lun2.

```
cluster1::> lun import delete -vserver vs0 -foreign-disk  
6000B5D0006A0000006A020E00040000
```

Deletes the import relationship of the foreign disk with serial number 6000B5D0006A0000006A020E00040000.

## Related Links

- [lun import stop](#)

# lun import pause

Pause the import for the specified LUN

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command pauses the data import to a specified LUN.

This command does not reset all import checkpoints. To resume a paused import, use the `lun import resume` command to retart from the last checkpoint taken before you paused the data import.

If you want to resume the data import from the beginning, use the `lun import stop` command. Then use the `lun import start` command.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver that contains the LUN you want to pause the data import to.

**-path <path> - LUN Path**

Specifies the path of the LUN you want to pause the data import to. Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtrees1/lun1`.

## Examples

```
cluster1::> lun import pause -vserver vs1 -path /vol/vol2/lun2
```

Pauses the data import for lun2 at the path /vol/vol2/lun2

# lun import prepare-to-downgrade

Prepares LUN import to be downgraded

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command prepares the cluster for a downgrade to a version of Data ONTAP earlier than 8.3.1 by disabling the online LUN import feature. Before using this command verify that all LUNs in an import relationships are offline by running [lun show](#).

## Examples

```
cluster1::> lun import prepare-to-downgrade
```

The above example will disable the online LUN import feature if all LUNs in import relationships are offline

## Related Links

- [lun show](#)

# lun import resume

Resume the import for the specified LUN

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

Resumes the data import to a specified LUN.

The import starts from the last checkpoint taken before you paused the data import.

If you want to resume the data import from the beginning, use the `lun import stop` command. Then use the `lun import start` command.

## Parameters

### **-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver that contains the LUN you want to resume the data import to.

### **-path <path> - LUN Path**

Specifies the path of the LUN that you want to resume the data import to. Examples of correct LUN paths are **/vol/vol1/lun1** and **/vol/vol1/qtree1/lun1**.

## Examples

```
cluster1::> lun import resume -vserver vs1 -path /vol/vol2/lun2
```

Resumes the data import to lun2 at the path /vol/vol2/lun2

## lun import show

Display a list of import relationships

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command displays information about the import relationships.

## Parameters

### **{ [-fields <fieldname>, ...]**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

### **[-instance ]}**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

### **[-vserver <Vserver Name>] - Vserver Name**

Displays import relationships for a specified Vserver.

### **[-foreign-disk <text>] - Foreign Disk Serial Number**

Enables you to see the import relationship for a particular foreign disk with the specified serial number.

### **[-path <path>] - LUN Path**

Enables you to see the import relationship for a particular LUN path. Examples of correct LUN

paths are `/vol/vol1/lun1` and `/vol/vol1/qtrees1/lun1` .

**`[-import-home-node {<nodename>|local}] - Import Home Node`**

Enables you to see the node that initially started the data import and where the I/O for the foreign disk is directed. If failover occurs, any in-progress data import restarts on the partner node.

**`[-import-current-node {<nodename>|local}] - Import Current Node`**

Displays the node that is currently importing data and where the I/O for the foreign disk is directed. During giveback and if the import home node is different from the current home node , import restarts on the initial node (import-home-node).

**`[-operation-in-progress {import|verify}] - Operation in Progress`**

Enables you to see the imports in progress or import verification in progress.

**`[-admin-state {stopped|started|paused}] - Admin State`**

Enables you to see the import relationships for a specified administrative state. For example, you can list all the imports that have started in a cluster.

**`[-operational-state {in_progress|failed|completed|stopped|paused}] - Operational State`**

Enables you to see the import relationships for a specified operational state. For example, you can list all the imports that have completed in a cluster.

**`[-percent-complete <integer>] - Percent Complete`**

Enables you to see the percentage of completion for both import and verification. If you want to see all the complete imports and verifications, you would specify 100.

**`[-imported-blocks <integer>] - Blocks Imported`**

Enables you to see the number of blocks that have been imported to the LUN.

**`[-compared-blocks <integer>] - Blocks Compared`**

Enables you to see the number of LUN and foreign disk blocks that have been compared.

**`[-total-blocks <integer>] - Total Blocks`**

Enables you to see the total number of blocks that must be imported to complete the data import to a LUN or the number of blocks that must be compared to complete the import verification.

**`[-estimated-remaining-duration {<seconds>|[<d> days] <hh>:<mm>[:<ss>]}] - Estimated Remaining Duration`**

If this parameter is specified, the command displays import or verify operations that match the specified time.

**`[-failure-reason <text>] - Failure Reason`**

Selects LUN import operations that match this parameter value.

**`[-max-throughput-limit {<integer>[KB|MB|GB|TB|PB]}] - Maximum Throughput Limit (per sec)`**

Selects the LUN import operations that match this parameter value. This value is the throughput

limit at which an import or verify will be throttled. By default, there is no throttling.

### **[-current-throughput {<integer>[KB|MB|GB|TB|PB]}] - Current Throughput (per sec)**

Selects the LUN import operations that match this parameter value. This value is the current throughput for an in-progress import or verify operation.

### **[-qos-policy-group <text>] - QoS Policy Group**

Selects the LUN import operations that match this parameter value. This value is the QoS policy group associated with an import relationship.

## Examples

```
cluster1::> lun import show
vserver          foreign-disk          path          operation-
in-progress      admin-state  operational-state  percent-complete
-----
vs1              6000B5D0006A0000006A020E00040000  /vol/dvol1/lun1  import

```

progress 5%

Display active LUN import sessions in a cluster.

## lun import start

Start the import for the specified LUN

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

This command initiates the data import to a specified LUN.

You must use the `lun import create` command to create an import relationship between a LUN and a foreign disk before you can initiate the data import.

### Parameters

**-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver that contains the LUN you want to import data to.

**-path <path> - LUN Path**

Specifies the path of the LUN that you want to import data to. Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtree1/lun1`.

### Examples

```
cluster1::> lun import start -vserver vs1 -path /vol/vol2/lun2
```

Starts the data import to `lun2` at the path `/vol/vol2/lun2`.

## lun import stop

Stop the import for the specified LUN

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

This command stops the data import into a specified LUN.

After you stop the data import and if you start the import again using `lun import start` command, then the import restarts from the beginning.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver that contains the LUN you want to stop importing data to.

**-path <path> - LUN Path**

Specifies the path of the LUN that you want to stop the data import to.

## Examples

```
cluster1::> lun import stop -vserver vs1 -path /vol/vol2/lun2
```

Stops data import to lun2 at the path /vol/vol2/lun2

## Related Links

- [lun import start](#)

# lun import throttle

Modify the max throughput limit for the specified import relationship

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command throttles the speed of the import for a given LUN by specifying a maximum throughput limit on the import.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver that contains the LUN to which data from the foreign disk is imported.

**-path <path> - LUN Path**

Specifies the path of the LUN to which data from the foreign disk is imported. Examples of correct LUN paths are **/vol/vol1/lun1** and **/vol/vol1/qtree1/lun1**.

**-max-throughput-limit {<integer>[KB|MB|GB|TB|PB]} - Maximum Throughput Limit (per sec)**

Specifies the maximum amount of throughput to be allocated for processing import requests on the bound LUN. At the time of creation, the default is zero. A value of zero implies that import traffic is processed by the system at best effort rate along with on-going user I/O. A non-zero value indicates that import will be throttled at a rate which is at most the maximum throughput limit set.

## Examples

```
cluster1::*> lun import throttle -vserver vs1 -path /vol/vol1/lun1 -max-throughput
-limit 3M
```

The above example limits the import speed for the bound LUN with path /vol/vol1/lun1 to a maximum of 3MB/s.

## lun import verify start

Start the verification of the foreign disk and LUN data

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command compares the LUN and the foreign disk block by block. You are not required to run this command; it is optional. Before you can do this verification process, the operation state must be stopped or completed. Use the `lun import show` command to determine the operation state.

If a block mismatch occurs, the verification process stops.

Verification must be done offline. Ensure the foreign disk and LUN cannot be accessed by a host. To prevent access of the LUN, the LUN should be taken offline administratively using the `lun offline` command.

Note: The specified LUN must be in an import relationship with a foreign disk before you can verify the data import.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver that contains the LUN you want to compare block by block with the foreign disk.

**-path <path> - LUN Path**

Specifies the path of the LUN that you want to compare the foreign disk to. Examples of correct LUN paths are `/vol/vol1/lun1` and `/vol/vol1/qtrees1/lun1`.

## Examples

```
cluster1::> lun import verify start -vserver vs1 -path /vol/vol2/lun2
```

Starts the import verification on lun2 at path /vol/vol2/lun2.

# lun import verify stop

Stop the verify for the specified LUN

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command stops the block by block verification of the foreign disk and LUN data.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver that contains the LUN you want to stop block by block comparison with the foreign disk.

**-path <path> - LUN Path**

Specifies the path of the LUN that you want to stop the block by block comparison. Examples of correct LUN paths are **/vol/vol1/lun1** and **/vol/vol1/qtree1/lun1**.

## Examples

```
cluster1::> lun import verify stop -vserver vs1 -path /vol/vol2/lun2
```

Stops the import verify on lun at path /vol/vol2/lun2.

# lun mapping add-reporting-nodes

Add Reporting Nodes

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command is used before or after a data mobility event that modifies the owning node of the LUN to add the new optimized nodes to the specified LUN mapping's reporting nodes.

For more information on managing reporting nodes in response to data mobility events, please see the Data ONTAP SAN Administration Guide.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

Specifies the name of the Vserver containing the LUN.

**{ -path <path> - LUN Path**

Specifies the path of the LUN. Examples of correct LUN paths are **/vol/vol1/lun1** and **/vol/vol1/qtrees1/lun1**.

**[ -volume <volume name> - Volume Name**

Specifies the volume that contains the LUN.

**[-qtree <qtree name>] - Qtree Name**

Specifies the qtree that contains the LUN.

**-lun <text> - LUN Name }**

Specifies the LUN name.

**-g, -igroup <text> - Igroup Name**

Specifies the igroup the LUN is mapped to.

**{ -local-nodes <>true> - Add Nodes for Current LUN Location**

Add the current LUN owner node and HA partner to the LUN mapping's reporting nodes.

This option should be used after a LUN mobility event to restore optimized access to the LUN.

**[ -destination-aggregate <aggregate name> - Add Nodes for Aggregate**

Add the specified aggregate's owner node and HA partner to the LUN mapping's reporting nodes.

This option may be used prior to a LUN mobility event that changes the LUN's containing aggregate.

**[ -destination-volume <volume name> - Add Nodes for Volume }**

Add the specified volume's owner node and HA partner to the LUN mapping's reporting nodes.

This option may be used prior to a LUN mobility event that changes the LUN's containing volume.

**[ -all <>true> - Add All Nodes }**

Set the LUN mapping to report on all nodes in preparation for a revert to a previous version of Data ONTAP.

## Examples

```
cluster1::> lun mapping add-reporting-nodes -vserver vs1 -path /vol/vol1/lun1 -igroup ig1
```

Add the current owner node and HA partner for the LUN mapping of **/vol/vol1/lun1** to igroup **ig1**

```
cluster1::> lun mapping add-reporting-nodes -vserver vs1 -volume vol1 -lun * -igroup
ig1 -destination-aggregate aggr2
```

Add the aggregate owner node and HA partner for aggregate **aggr2** to all LUN mappings in volume **vol1** to igroup **ig1** prior to starting a volume move operation.

## lun mapping create

Map a LUN to an initiator group

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

### Description

This command maps a LUN to all of the initiators in an initiator group (igroup). After you map the LUN, the LUN is visible to all initiators in the igroup.

Data ONTAP ensures that there are no LUN map conflicts whether the LUN is offline or online. A LUN map conflict is a mapping that would violate either of the following rules:

- Each LUN can be mapped to an initiator only once. A LUN can be mapped to multiple igroups as long as each igroup has a distinct set of initiators.
- LUN IDs must be unique such that every initiator has a unique ID for each LUN to which it is mapped. If you map a LUN to an igroup, the LUN ID for that mapping cannot be reused by any of the initiators in that igroup.

In order to determine if a LUN ID is valid for a mapping, Data ONTAP checks each initiator in the igroup to make sure that the LUN ID is not used for another mapping that includes that initiator.

Prior to mapping a LUN, you must have at least one iSCSI or FCP LIF provisioned on the LUN's owner node and high-availability partner node.

### Parameters

**-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver that contains the LUN you want to map.

**{ -path <path> - LUN Path**

Specifies the path of the LUN that you want to map. Examples of correct LUN paths are **/vol/vol1/lun1** and **/vol/vol1/qtrees1/lun1**.

**| -volume <volume name> - Volume Name**

Specifies the volume that contains the LUN you want to map.

**[-qtree <qtree name>] - Qtree Name**

Specifies the qtree that contains the LUN you want to map.

**-lun <text> - LUN Name }**

Specifies the LUN name that you want to map.

**-g, -igroup <text> - Igroup Name**

Specifies the igroup that you want to map.

**[-lun-id <integer>] - LUN ID**

Specifies the LUN ID for the mapping. The LUN ID is specific to the mapping, not to the LUN itself. This is used by the initiators in the igroup as the Logical Unit Number for the initiator when accessing the storage.

**[-additional-reporting-node <nodename>] - Additional Reporting Node**

Specifies an additional node to populate the **-reporting-nodes** list when creating the LUN mapping. The specified node's high availability partner will be automatically populated as well. Use this parameter when preferred data mobility destinations are known ahead of time and the appropriate paths can be pre-configured.

## Examples

```
cluster1::> lun mapping create -vserver vs1 -path /vol/vol1/lun1 -igroup ig1 -lun-id 8
```

Maps a LUN at /vol/vol1/lun1 on Vserver vs1 to the igroup ig1 with LUN ID 8.

## lun mapping delete

Unmap a LUN from an initiator group

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command unmaps a LUN from an initiator group. After you use this command, the LUN is not visible to any of the initiators in the initiator group.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

Selects the LUN maps for the Vserver that matches the parameter value.

**{ -path <path> - LUN Path**

Specifies the path of the LUN you want to unmap. Examples of correct LUN paths are **/vol/vol1/lun1** and **/vol/vol1/qtrees1/lun1**.

**| -volume <volume name> - Volume Name**

Specifies the volume of the LUN you want to unmap.

**-qtree <qtree name> - Qtree Name**

Specifies the qtree of the LUN you want to unmap.

**-lun <text> - LUN Name }**

Specifies the name of the LUN you want to unmap.

**-g, -igroup <text> - Igroup Name**

Specifies the initiator group that you want to unmap the LUN from.

## Examples

```
cluster1::> lun mapping delete -vserver vs1 -path /vol/vol1/lun1 -igroup ig1
```

Unmaps LUN at path /vol/vol1/lun1 from the initiator group ig1 on Vserver vs1.

# lun mapping remove-reporting-nodes

## Remove Reporting Nodes

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command is used after a data mobility event to remove reporting nodes that are no longer required for optimized access from the specified LUN mapping.

For more information on managing reporting nodes in response to data mobility events, please see the Data ONTAP SAN Administration Guide.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

Specifies the name of the Vserver containing the LUN.

**{ -path <path> - LUN Path**

Specifies the path of the LUN. Examples of correct LUN paths are **/vol/vol1/lun1** and **/vol/vol1/qtrees1/lun1**.

**| -volume <volume name> - Volume Name**

Specifies the volume that contains the LUN.

**[-qtree <qtree name>] - Qtree Name**

Specifies the qtree that contains the LUN.

**-lun <text> - LUN Name }**

Specifies the LUN name.

**-g, -igroup <text> - Igroup Name**

Specifies the igroup the LUN is mapped to.

**-remote-nodes <true> - Remove Remote Nodes for LUN Location**

If specified, remove all nodes other than the LUN's owner and HA partner from the LUN mapping's reporting nodes.

## Examples

```
cluster1::> lun mapping remove-reporting-nodes -vserver vs1 -path /vol/vol1/lun1
-igroup ig1
```

Remove excess remote nodes from the LUN mapping of **/vol/vol1/lun1** to igroup **ig1**

# lun mapping show-initiator

Show the LUN mappings to a specific initiator

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

The **lun mapping show-initiator** command lists the LUNs which are mapped to an initiator group which contains a specific initiator.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-vserver <Vserver Name>] - Vserver Name**

Selects the LUN mappings for the vserver that you specify.

**-initiator <text> - Initiator Name**

Selects the LUN mappings for the initiator that you specify.

**[-lun-id <integer>] - Logical Unit Number**

Selects the LUN mappings with a LUN ID that you specify.

**[-igroup <text>] - Igroup Name**

Selects the LUN mappings for the initiator group that you specify.

**[-path <path>] - LUN Path**

Selects the LUN mappings for the LUN path that you specify.

**[-node <nodename>] - LUN Node**

Selects the LUN mappings for the LUNs which are being hosted on the node that you specify.

**[-reporting-nodes <nodename>, ...] - Reporting Nodes**

Selects the LUN mappings for the LUNs which have reporting nodes that you specify.

**[-vserver-uuid <UUID>] - Vserver UUID**

Selects the LUN mappings for the Vserver UUID that you specify.

**[-igroup-uuid <UUID>] - Igroup UUID**

Selects the LUN mappings for the initiator group UUID that you specify.

**[-lun-uuid <UUID>] - LUN UUID**

Selects the LUN mappings for the LUN UUID that you specify.

## Examples

The following example displays the LUN mappings for initiator **20:10:0a:50:00:01:01:01** in Vserver **vs1**.

```
cluster1::> lun mapping show-initiator -vserver vs1 -initiator 20:10:0a:50:00:01:01:01
Vserver Initiator LUN ID Path                               IGroup
-----
vs1      20:10:0a:50:00:01:01:01
          0 /vol/igroup_1_1_vol/lun1                            igroup_1
          2 /vol/igroup_1_1_vol/lun3                            igroup_1
          3 /vol/igroup_1_2_vol/lun1                            igroup_1
          5 /vol/igroup_1_2_vol/lun3                            igroup_1
          6 /vol/igroup_1_3_vol/lun1                            igroup_1
          8 /vol/igroup_1_3_vol/lun3                            igroup_1
          9 /vol/igroup_1_4_vol/lun1                            igroup_1
         11 /vol/igroup_1_4_vol/lun3                            igroup_1
         12 /vol/igroup_2_1_vol/lun1                            igroup_2
```

```

14 /vol/igroup_2_1_vol/lun3      igroup_2
15 /vol/igroup_2_2_vol/lun1      igroup_2
17 /vol/igroup_2_2_vol/lun3      igroup_2
18 /vol/igroup_2_3_vol/lun1      igroup_2
20 /vol/igroup_2_3_vol/lun3      igroup_2
21 /vol/igroup_2_4_vol/lun1      igroup_2
23 /vol/igroup_2_4_vol/lun3      igroup_2

```

16 entries were displayed.

## lun mapping show

Lists the mappings between LUNs and initiator groups.

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command lists the mappings between LUNs and initiator groups.

## Parameters

{ [-fields <fieldname>, ...]

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

| [-instance ] }

If you specify the **-instance** parameter, the command displays detailed information about all fields.

[-vserver <Vserver Name>] - Vserver Name

Selects the LUN maps for the Vserver that matches the parameter value.

{ [-path <path>] - LUN Path

Selects the LUN maps for the LUN with the path that matches the parameter value. Examples of correct LUN paths are **/vol/vol1/lun1** and **/vol/vol1/qtree1/lun1** .

| [-volume <volume name>] - Volume Name

Selects the LUN maps for the volumes that match the parameter value.

[-qtree <qtree name>] - Qtree Name

Selects the LUN maps for the queue trees that match the parameter value.

[-lun <text>] - LUN Name }

Selects the LUN maps for the LUNs with a name that matches the parameter value.

**[-g, -igroup <text>] - Igroup Name**

Selects the LUN maps for the igroup that matches the parameter value.

**[-ostype <Initiator Group OS Type>] - Igroup OS Type**

Selects the LUN maps for the initiator groups with the OS type that matches the parameter value.

**[-protocol <protocol\_enum>] - Igroup Protocol Type**

Selects the LUN maps for initiator groups with a protocol that matches the parameter value. Possible values include FCP, iSCSI, or mixed.

**[-lun-id <integer>] - LUN ID**

Selects the LUN maps with a LUN ID that matches the parameter value.

**[-portset <text>] - Portset Binding Igroup**

Selects the LUN maps for initiator groups bound to the portset that matches the parameter value.

**[-alua {true|false}] - ALUA**

Selects the LUN maps with ALUA settings that match the parameter value.

**[-n, -initiators <text>,...] - Initiators**

Selects the LUN maps for initiator groups containing the initiators that match the parameter value.

**[-node <nodename>] - LUN Node**

Selects the LUN maps for nodes that match the parameter value.

**[-reporting-nodes <nodename>,...] - Reporting Nodes**

Selects the LUN maps that match the parameter value.

## Examples

```
cluster1::> lun mapping show
Vserver      Path                               Igroup  LUN ID  Protocol
-----
vs1          /vol/vol1/lun1                    igroup1  10     mixed
vs1          /vol/vol1/lun1                    igroup2   4     mixed
vs1          /vol/vol15/lun1                   igroup3   6     mixed
vs1          /vol/vol15/lun2                   igroup3   1     mixed
4 entries were displayed.
```

The example above lists all of the mappings between LUNs and initiator groups and the LUN ID for each mapping.

## lun move cancel

Cancel a LUN move operation before the new LUN has been created

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

The **lun move cancel** command cancels an ongoing LUN move operation prior to creation of the new LUN. The command fails if the LUN already exists at the destination path; in that case, allow the current move operation to complete and then move it back using the [lun move start](#) command.

All data transfers will be halted. If the source LUN was quiesced, it will be restored to normal operation.

This is an advanced command because the preferred way to cancel a LUN move operation is to wait until the new LUN becomes visible, and then move it back.

## Parameters

**{ -vserver <Vserver Name> - Vserver Name**

Specifies the name of the Vserver that will host the destination LUN.

**-destination-path <path> - Destination Path**

Specifies the full path to the new LUN, in the format `/vol/<volume>[/<qtree>]/<lun>`.

## Examples

```
cluster1::*> lun move cancel -vserver vs1 -destination-path /vol/vol2/lun2
```

Cancels the move operation identified by Vserver **vs1** and destination path **/vol/vol2/lun2**.

## Related Links

- [lun move start](#)

# lun move modify

Modify an ongoing LUN move operation

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **lun move modify** command modifies the maximum throughput of an ongoing move operation.

## Parameters

**{ -vserver <Vserver Name> - Vserver Name**

Specifies the name of the Vserver that will host the destination LUN.

**-destination-path <path> - Destination Path**

Specifies the full path to the new LUN, in the format /vol/<volume>[/<qtree>]/<lun>.

**-max-throughput {<integer>[KB|MB|GB|TB|PB]} - Maximum Transfer Rate (per sec)**

Specifies the maximum amount of data, in bytes, that can be transferred per second in support of this operation. This mechanism can be used to throttle a transfer, to reduce its impact on the performance of the source and destination nodes.

The specified value will be rounded up to the nearest megabyte.

## Examples

```
cluster1::> lun move modify -vserver vs1 -destination-path /vol/vol2/lun2 -max  
-throughput 25MB
```

Modifies the maximum throughput for the ongoing move job identified by Vserver **vs1** and destination path **/vol/vol2/lun2** to 25 MB/sec.

## lun move pause

Pause an ongoing LUN move operation

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **lun move pause** command pauses an ongoing move operation. Use the [lun move resume](#) command to resume the move operation.

## Parameters

**{ -vserver <Vserver Name> - Vserver Name**

Specifies the name of the Vserver that will host the destination LUN.

**-destination-path <path> - Destination Path**

Specifies the full path to the new LUN, in the format /vol/<volume>[/<qtree>]/<lun>.

## Examples

```
cluster1::> lun move pause -vserver vs1 -destination-path /vol/vol2/lun2
```

Pauses the ongoing move operation identified by Vserver **vs1** and destination path **/vol/vol2/lun2** .

## Related Links

- [lun move resume](#)

## lun move resume

Resume a paused LUN move operation

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `lun move resume` command resumes a paused move operation.

## Parameters

**{ -vserver <Vserver Name> - Vserver Name**

Specifies the name of the Vserver that will host the destination LUN.

**-destination-path <path> - Destination Path**

Specifies the full path to the new LUN, in the format `/vol/<volume>[/<qtree>]/<lun>`.

## Examples

```
cluster1::> lun move resume -vserver vs1 -destination-path /vol/vol2/lun2
```

Resumes the paused move operation identified by Vserver **vs1** and destination path **/vol/vol2/lun2** .

## lun move show

Display a list LUNs currently being moved

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `lun move show` command shows information about LUNs currently being moved in the cluster.

## Parameters

`{ [-fields <fieldname>, ... ] }`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

`[ [-instance ] ] }`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-vserver <Vserver Name>] - Vserver Name`

Selects LUN move operations that match this parameter value.

`[-destination-path <text>] - Destination Path`

Selects LUN move operations that match this parameter value.

`[-source-path <path>] - Source Path`

Selects LUN move operations that match this parameter value.

`[-is-promoted-late {true|false}] - Is Destination Promoted Late`

Selects LUN move operations that match this parameter value.

`[-max-throughput {<integer>[KB|MB|GB|TB|PB]}] - Maximum Transfer Rate (per sec)`

Selects LUN move operations that match this parameter value.

`[-job-status {Preparing|Allocation-Map|Data|Destroying|Paused-Manual|Paused-Error|Complete|Destroyed|Terminated-Manual}] - LUN Move Status`

Selects LUN move operations that match this parameter value. The possible values are:

- **Preparing** - the LUN move job is in Preparing status.
- **Allocation-Map** - the LUN move job is in Allocating status.
- **Data** - the LUN move job is in Moving Data status.
- **Destroying** - the LUN move job is in Destroying status.
- **Paused-Manual** - the LUN move job is in Manually Paused status.
- **Paused-Error** - the LUN move job is in Paused By Error status.
- **Complete** - the LUN move job is in Complete status.
- **Destroyed** - the LUN move job is in Destroyed status.
- **Terminated-Manual** - the LUN move job is in Manually Terminated status.

**[-progress-percent <percent>] - LUN Move Progress (%)**

Selects LUN move operations that match this parameter value.

**[-elapsed-time <time\_interval>] - Elapsed Time**

Selects LUN move operations that match this parameter value.

**[-cutover-time <time\_interval>] - Cutover Time**

Selects LUN move operations that match this parameter value.

**[-is-snapshot-fenced {true|false}] - Is Snapshot Fenced**

Selects LUN move operations that match this parameter value.

**[-is-destination-ready {true|false}] - Is Destination Ready**

Selects LUN move operations that match this parameter value.

**[-last-failure-reason <text>] - Last Failure Reason**

Selects LUN move operations that match this parameter value.

## Examples

```
cluster1::> lun move show
Vserver   Destination Path           Status      Progress
-----
vs1       /vol/vol2/lun1           Data        35%
vs1       /vol/vol2/lun2           Complete    100%
2 entries were displayed.
```

The example above displays information about all the LUN move operations in the cluster.

```
cluster1::> lun move show -vserver vs1 -destination-path /vol/vol2/lun1 -instance
Destination Vserver Name: vs1
      Destination Path: /vol/vol2/lun1
      Source Path: /vol/vol1/lun1
Is Destination Promoted Early: false
Maximum Transfer Rate (per sec): 0B
      LUN Move Status: Data
LUN Move Progress (%): 35%
      Elapsed Time: 145s
      Cutover Time (secs): 0s
      Is Snapshot Fenced: true
      Is Destination Ready: true
      Last Failure Reason: -
```

The example above displays all information about the LUN being moved to **/vol/vol2/lun1** in Vserver **vs1**.

# lun move start

Start moving a LUN from one volume to another within a Vserver

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **lun move start** command initiates moving of a LUN from one volume to another. The destination volume can be located on the same node as the original volume or on a different node.

Use [lun move-in-volume](#) command if you want to rename the LUN or move it within the same volume.

This command does not support movement of LUNs that are created from files.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

Specifies the name of the Vserver that will host the new LUN.

**[-destination-path <path> - Destination Path**

Specifies the full path to the new LUN, in the format `/vol/<volume>[/<qtree>]/<lun>`.

**-source-path <path> - Source Path }**

Specifies the full path to the source LUN, in the format `/vol/<volume>[/<qtree>]/<lun>`.

**[-promote-late <true>] - Promote Late**

Optionally specifies that the destination LUN needs to be promoted late.

If the destination is promoted early, the new LUN will be visible immediately. However, Snapshot copies of the volume containing the new LUN cannot be taken until the LUN move operation reaches 'Moving Data' status.

If the destination is promoted late, the new LUN will be visible only after it has been fully framed. However, the LUN move job will not block the creation of Snapshot copies of the volume containing the new LUN.

If this parameter is not specified, the destination LUN will be promoted early.

**[-max-throughput {<integer>[KB|MB|GB|TB|PB]}] - Maximum Transfer Rate (per sec)**

Optionally specifies the maximum amount of data, in bytes, that can be transferred per second in support of this operation. This mechanism can be used to throttle a transfer, to reduce its impact on the performance of the source and destination nodes.

If this parameter is not specified, throttling is not applied to the data transfer.

The specified value will be rounded up to the nearest megabyte.

## Examples

```
cluster1::> lun move start -vserver vs1 -destination-path /vol/vol2/lun2 -source-path /vol/vol1/lun1
```

Starts moving LUN **lun1** from volume **vol1** in Vserver **vs1** to **lun2** on volume **vol2** in Vserver **vs1** .

## Related Links

- [lun move-in-volume](#)

# lun persistent-reservation clear

Clear the SCSI-3 persistent reservation information for a given LUN

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

Clears the persistent reservation for the specified LUN.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver.

**{ -path <path> - LUN Path**

Specifies the path of the LUN. Examples of correct LUN paths are **/vol/vol1/lun1** and **/vol/vol1/qtrees1/lun1** .

**| -volume <volume name> - Volume Name**

Specifies the volume.

**-lun <text> - LUN Name**

Specifies the name of the LUN.

**[-mtree <mtree name>] - Mtree Name }**

Specifies the mtree.

## Examples

```
cluster1::*> lun persistent-reservation clear -vserver vs_1 -path /vol/vol_1/lun_1
```

Clears the persistent reservation data for lun lun\_1 in volume vol\_1 for Vserver vs\_1.

## lun persistent-reservation show

Display the current reservation information for a given LUN

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

Displays reservation information for a specified LUN in a Vserver. Unlike other show commands, the user must specify the LUN.

## Parameters

{ [-fields <fieldname>, ...]

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

| [-instance ] }

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver.

{ **-path <path> - LUN Path**

Specifies the path of the LUN. Examples of correct LUN paths are **/vol/vol1/lun1** and **/vol/vol1/qtree1/lun1**.

| **-volume <volume name> - Volume Name**

Specifies the volume.

**-lun <text> - LUN Name**

Specifies the name of the LUN.

{ **-qtree <qtree name>] - Qtree Name }**

Specifies the qtree.

**[-scsi-revision {scsi2|scsi3}] - SCSI Revision**

Selects the reservations that match this parameter value.

**[-entry-type {reservation|registration}] - Reservation or Registration**

Selects the reservations that match this parameter value.

**[-protocol {fc|iscsi}] - Protocol**

Selects the reservations that match this parameter value.

**[-reservation-key <text>] - Reservation Key**

Selects the reservations that match this parameter value.

**[-reservation-type-code <text>] - Reservation Type**

Selects the reservations that match this parameter value. The possible values for SCSI-3 reservations are:

- write exclusive
- exclusive access
- write exclusive registrants only
- exclusive access registrants only
- write exclusive all registrants
- exclusive access all registrants

and for SCSI-2 are:

- regular
- third party

**[-initiator-name <text>] - Initiator Name**

Selects the reservations that match this parameter value.

**[-aptp1 {true|false}] - Persist Through Power Loss**

Selects the reservations that match this parameter value. If **true**, the reservation will be preserved over a power loss. If **false**, it will not. This value is for SCSI-3 reservations only.

**[-target-wwpn <text>] - FCP Target WWPN**

Selects the reservations that match the specified World Wide Port Name (WWPN).

**[-isid <text>] - Initiator Session ID**

Selects the reservations that match this parameter value.

**[-tpgroup-tag <integer>] - TPGroup Tag**

Selects the reservations that match the specified target portal group tag. The tag identifies the tpgroup the reservation was made over.

**[-third-party-initiator-name <text>] - Third Party Initiator Name**

Selects the reservations that match this parameter value (the initiator name that the reservation

was made for). This is specific to third party reservation types, which is indicated by reservation-type-code.

## Examples

```
cluster1::*> lun persistent-reservation show -vserver vs_1 /vol/vol_1/lun_1
  Key                               Protocol Type                Initiator Name
-----
  APTPL: true
  a0:00:00:00:00:00:00:01 iscsi   write exclusive             iqn.1993-
08.org.debian:01:fa752b8a5a3a
  a0:00:00:00:00:00:00:01 iscsi   -                            iqn.1993-
08.org.debian:01:fa752b8a5a3a
  2 entries were displayed.
```

The example above displays the current reservations for lun\_1 on Vserver vs\_1.

## lun portset add

Add iSCSI/FCP LIFs to a portset

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command adds existing iSCSI and FCP LIFs to a portset. To create a new portset, use the [lun portset create](#) command.

Use the [network interface create](#) command to create new LIFs.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver.

**-portset <text> - Portset Name**

Specifies the portset you want to add the LIFs to.

**-port-name <port\_name>, ... - LIF or TPG Name**

Specifies the LIF name you want to add to the portset.

## Examples

```
cluster1::> portset add -vserver vs1 -portset ps1 -port-name lif1
```

Adds port lif1 to portset ps1 on Vserver vs1.

## Related Links

- [lun portset create](#)
- [network interface create](#)

# lun portset create

Creates a new portset

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command creates a new portset for FCP and iSCSI. The portset name can include a maximum of 96 characters. You can add LIFs to the new portset. If you do not add a LIF to the portset, you create an empty portset. To add LIFs to an existing portset, use the [lun portset add](#) command.

After you create a portset, you must bind the portset to an igroup so the host knows which FC or iSCSI LIFs to access. If you do not bind an igroup to a portset, and you map a LUN to an igroup, then the initiators in the igroup can access the LUN on any LIF on the Vserver.

You cannot bind an igroup to an empty portset because the initiators in the igroup would have no LIFs to access the LUN.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver.

**-portset <text> - Portset Name**

Specifies the name of the new portset. A portset name is a case-sensitive name that must contain one to 96 characters. Spaces are not allowed.

**[-port-name <port\_name>,...] - LIF Or TPG Name**

Specifies the name of the logical interface that you want to add to the portset you want to create.

**{ [-protocol {mixed|fcp|iscsi}] - Protocol**

Specifies if the portset protocol type is **fcp**, **iscsi**, or **mixed**. The default is **mixed**.

**| [-f, -fcp <true>] -FCP**

Specifies FCP as the protocol type of the new portset.

**| [-i, -iscsi <true>] -iSCSI }**

Specifies iSCSI as the protocol type of the new portset.

## Examples

```
cluster1::> portset create -vserver vs1 -portset ps1 -protocol mixed
```

Creates a portset **ps1** on Vserver **vs1** with the protocol type of **mixed** .

```
cluster1::> portset create -vserver vs1 -portset iscsips -protocol iscsi
```

Creates a portset **iscsips** on Vserver **vs1** with the protocol type of **iscsi** .

```
cluster1::> portset create -vserver vs1 -portset fcppc -protocol fcp
```

Creates a portset **fcppc** on Vserver **vs1** with the protocol type of **fcp** .

```
cluster1::> portset create -vserver vs1 -portset ps2 -protocol mixed -port-name l11
```

Creates a portset **ps2** on Vserver **vs1** with the protocol type of **mixed** and LIF **l11** .

## Related Links

- [lun portset add](#)

# lun portset delete

Delete the portset

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command deletes an existing portset. By default, you cannot delete a portset if it is bound to an initiator group. If a portset is bound to an initiator group, you can do one of the following:

- specify the **force** option to unbind the portset from the initiator group and delete the portset.
- use the [lun igroup unbind](#) command to unbind the portset from the initiator group. Then you can

delete the portset.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver.

**-portset <text> - Portset Name**

Specifies the portset you want to delete.

**[-f, -force <>true>] - Force**

Forcibly unbinds the portset from the initiator group.

## Examples

```
cluster1::> portset delete -vserver vs1 -portset ps1
```

Deletes portset ps1 on Vserver vs1.

## Related Links

- [lun igroup unbind](#)

# lun portset remove

Remove iSCSI/FCP LIFs from a portset

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command removes a LIF from a portset.

You cannot remove the last LIF in a portset if the portset is bound to an initiator group (igroup). To remove the last LIF in a portset, use the [lun igroup unbind](#) command to unbind the portset from the igroup. Then you can remove the last LIF in the portset.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

Specifies the Vserver.

**-portset <text> - Portset Name**

Specifies the portset you want to remove a LIF from.

**-port-name <port\_name>,... - LIF or TPG Name**

Specifies the LIF name you want to remove from the portset.

## Examples

```
cluster1::> portset remove -vserver vs1 -portset ps1 -port-name lif1
```

Removes port lif1 from portset ps1 on Vserver vs1.

## Related Links

- [lun igroup unbind](#)

# lun portset show

Displays a list of portsets

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command displays the LIFs in a portset. By default, the command displays all LIFs in all portsets.

## Parameters

**{ [-fields <fieldname>,...]**

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[-instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-vserver <Vserver Name>] - Vserver Name**

Selects the portsets that match this parameter value.

**[-portset <text>] - Portset Name**

Selects the portsets that match this parameter value.

**[-uuid <UUID>] - Portset Uuid**

Selects the portsets that match this parameter value.

**[-port-name <port\_name>,...] - LIF Or TPG Name**

Selects the portsets that match this parameter value.

**[-protocol {mixed|fcp|iscsi}] - Protocol**

Selects the portsets that match this parameter value.

**[-port-count <integer>] - Number Of Ports**

Selects the portsets that match this parameter value.

**[-igroups <igroup>,...] - Bound To Igroups**

Selects the portsets that match this parameter value.

## Examples

```
cluster1::> lun portset show
Vserver  Portset      Protocol Port Names      Igroups
-----
vs1      ps0          mixed   lif1, lif2       igroup1
         ps1          iscsi   lif3              igroup2
         ps2          fcp     lif4              -
3 entries were displayed.
```

The example above displays all portsets.

```
cluster1::> lun portset show -port-count 0
Vserver  Portset      Protocol Port Names      Igroups
-----
vs1      p1           iscsi   -                 -
```

The example above displays the portsets that contain zero LIFs.

```
cluster1::> lun portset show -protocol iscsi
Vserver  Portset      Protocol Port Names      Igroups
-----
vs1      p1           iscsi   -                 -
vs1      iscsips      iscsi   lif1              igroup1
2 entries were displayed.
```

The example above displays the portsets that have the iSCSI protocol.

```
cluster1::> lun portset show -port-name lif1
Vserver  Portset      Protocol Port Names      Igroups
-----
```

```
vs1      iscsips      iscsi      lif1      igroup1
```

The example above displays the portsets that contain LIF lif1.

## lun transition show

Display the status of LUN transition processing

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

The **lun transition show** command displays information about the LUN transition processing status of volumes. If no parameters are specified, the command displays the following information about all volumes:

- Vserver name
- Volume name
- Transition status

### Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[ [-instance ] ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-vserver <Vserver Name>] - Vserver Name**

Selects the volumes in the specified Vserver.

**[-volume <volume name>] - Volume Name**

Selects the volumes with the specified name.

**[-status {none|complete|failed|active}] - Transition Status**

Selects the volumes that match the specified transition status. The possible status values are:

- **active** - The volume is in an active SnapMirror transition relationship and not yet transitioned.
- **complete** - LUN transition has completed for the volume.
- **failed** - LUN transition has failed for the volume.
- **none** - The volume did not contain LUNs to transition from Data ONTAP 7-Mode.

**[-vserver <UUID>] - Vserver UUID**

Selects the volumes in the Vserver that matches the specified UUID.

**[-node <nodename>] - Filer ID**

Selects the volumes that match the specified node.

## Examples

The following example displays LUN transition information for all volumes in a Vserver named **vs1** :

```
cluster1::*> lun transition show -vserver vs1
Vserver          Volume          Transition Status
-----
vs1              vol0            none
                vol1            complete
                vol2            failed
                vol3            active
4 entries were displayed.
```

## lun transition start

### Start LUN Transition Processing

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **lun transition start** command starts LUN transition for the specified volume. Normally, transition is started automatically when **snapmirror break** is issued for the volume, this command allows restarting in the event automatic transitioning was interrupted or failed.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

The name of the Vserver containing the volume. If only one data Vserver exists, you do not need to specify this parameter.

**-volume <volume name> - Volume Name**

The name of the volume to restart LUN transition.

## Examples

The following example starts LUN transition on a volume named **volume1** in a Vserver named **vs1** :

```
cluster1::*> lun transition start -vserver vs1 -volume volume1
```

## Related Links

- [snapmirror break](#)

# lun transition 7-mode delete

Delete an Untransitioned 7-Mode LUN

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `lun transition 7-mode delete` command deletes an untransitioned LUN copied from a Data ONTAP 7-Mode system. This allows the admin to recover space from the volume for LUNs that may not be transitioned to clustered Data ONTAP without disrupting LUNs that have transitioned, for example, if the LUN is an unsupported OS type.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

This specifies the name of the Vserver from which the LUN is to be deleted. If only one data Vserver exists, you do not need to specify this parameter.

**-path <path> - LUN Path**

This specifies the path to the LUN to delete.

## Examples

The following example deletes the LUN `/vol/vol1/lun1` in a Vserver named `vs1` :

```
cluster1::*> lun transition 7-mode delete -vserver vs1 -path /vol/vol1/lun1
```

# lun transition 7-mode show

Display the 7-Mode LUN Inventory

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `lun transition 7-mode show` command displays information about LUNs copied from a Data ONTAP 7-Mode system. If no parameters are specified, the command displays the following information about all 7-Mode LUNs:

- Vserver name
- LUN path
- Operating system type
- Size
- Whether or not the LUN has been transitioned to clustered Data ONTAP

## Parameters

`{ [-fields <fieldname>, ... ] }`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

`[ -instance ] }`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-vserver <Vserver Name>] - Vserver Name`

Selects the 7-Mode LUNs in the specified Vserver.

`[-path <path>] - LUN Path`

Selects the 7-Mode LUNs with the specified path.

`[-volume <volume name>] - Volume Name`

Selects the 7-Mode LUNs that match the specified volume.

`[-ostype <LUN Operating System Format>] - OS Type`

Selects the 7-Mode LUNs that match the specified operating system type.

`[-size <size>] - LUN Size`

Selects the 7-Mode LUNs that match the specified size.

`[-prefix-size <size>] - Prefix Stream Size`

Selects the 7-Mode LUNs that match the specified prefix stream size.

`[-suffix-size <size>] - Suffix Stream Size`

Selects the 7-Mode LUNs that match the specified suffix stream size.

`[-serial <text>] - Serial Number`

Selects the 7-Mode LUNs that match the specified serial number for clustered Data ONTAP. LUNs where `is-transitioned` is `false` do not have a serial number assigned for clustered Data ONTAP.

**[-uuid <UUID>] - UUID**

Selects the 7-Mode LUNs that match the specified UUID for clustered Data ONTAP. LUNs where **is-transitioned** is **false** do not have a UUID assigned for clustered Data ONTAP.

**[-serial-7-mode <text>] - 7-mode Serial Number**

Selects the 7-Mode LUNs that match the specified serial number from 7-Mode.

**[-is-transitioned {true|false}] - Transition Complete**

Selects the 7-Mode LUNs that match the specified transition state. LUNs where this value is **true** have been transitioned and are available to be mapped for client access. LUNs where this value is **false** have not yet been transitioned and may not be mapped.

**[-vserver-uuid <UUID>] - Vserver UUID**

Selects the 7-Mode LUNs that match the specified Vserver UUID.

**[-node <nodename>] - Node**

Selects the 7-Mode LUNs that match the specified node name.

## Examples

The following example displays a summary of all 7-Mode LUNs for the volume **vol1** in a Vserver named **vs1**:

```
cluster1::*> lun transition 7-mode show -vserver vs1 -volume vol1
Vserver  Path                                Type    Size  Transitioned
-----  -
vs1      /vol/vol1/lun1                      linux   10MB  false
         /vol/vol1/lun2                      linux   500MB true
         /vol/vol1/lun3                      linux   500MB true
8 entries were displayed.
```

The following example displays detailed information for the 7-Mode LUN **/vol/vol1/lun2** in a Vserver named **vs1**:

```
cluster1::*> lun transition 7-mode show -vserver vs1 -path /vol/vol1/lun2
Vserver Name: vs1
  LUN Path: /vol/vol1/lun2
  Volume Name: vol1
  OS Type: linux
  LUN Size: 500MB
Prefix Stream Size: 0
Suffix Stream Size: 0
  Serial Number: BCVvv$DLZu8g
  UUID: f53d603b-9663-4567-9680-95c1a9cc6d9e
7-mode Serial Number: C4eqKotPI8Ui
Transition Complete: true
  Vserver UUID: be4cc135-163f-11e3-931f-123478563412
```

# metrocluster configure

Configure MetroCluster and start DR mirroring for the node and its DR group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **metrocluster configure** command creates a MetroCluster configuration on either all the nodes in both MetroCluster clusters or solely on nodes in a DR group. The command configures a HA partner, DR partner, and a DR auxiliary partner for the nodes and also starts NVRAM mirroring between the configured DR partner nodes.

In MetroCluster, a DR group is a group of four nodes, two in each of the MetroCluster clusters:

- In the local cluster, a node and its HA partner,
- In the peer cluster, a node and its HA partner. These nodes are DR partners to the nodes in the local cluster.

In a two node MetroCluster configuration, a DR group is a group of two nodes, one in each of the MetroCluster clusters.

There can be several DR groups in the MetroCluster configuration. MetroCluster provides synchronous DR protection to all data sets belonging to nodes within a properly configured DR group.

Without the **-node** parameter, the **metrocluster configure** command configures all the DR groups in both the MetroCluster clusters.

With the **-node`mynode** parameter, the command configures both the **mynode** node and its HA partner node from the local cluster, and its DR partner and DR auxiliary partner from the peer cluster.

Before running the **metrocluster configure** command, the aggregates and Vservers on each node must be prepared for the MetroCluster configuration. Each node should have:

- At least one non-root, mirrored aggregate of size greater than 10GB. This non-root aggregate should not have any volumes in it.
- No other non-root aggregates. Any other non-root, unmirrored aggregates and volumes should be deleted.
- No Vservers other than Vservers of type "node" or "admin." Any Vservers that are not of type "node" or "admin" should be deleted.
- A mirrored and healthy root aggregate.

After the command is successful all nodes in the local and remote clusters will have HA, DR, and DR

auxiliary partners and NVRAM mirroring between the DR partners will be turned on. The same conditions apply before running the `metrocluster configure-node`mynode`` command, except that only one DR group is configured.

For a MetroCluster over IP configuration, the `metrocluster configuration-settings` commands must be completed before using the `metrocluster configure` command. The commands required to be completed are:

- [`metrocluster configuration-settings dr-group create`](#)
- [`metrocluster configuration-settings interface create`](#)
- [`metrocluster configuration-settings connection connect`](#)

## Parameters

### `[-node-name {<nodename>|local}] - Node to Configure`

This optional parameter specifies the name of a single node in the local cluster. The command creates MetroCluster configuration on the local node specified by this parameter and the three other nodes belonging to the same DR group.

### `[-refresh {true|false}] - Refresh Configuration`

This optional parameter specifies if the node partner configuration steps should be done again. Not specifying this parameter will cause the MetroCluster configuration to continue using the current node partner information.

### `[-allow-with-one-aggregate {true|false}] - Override the Two Data Aggregates Requirement`

This optional parameter specifies if MetroCluster configuration should be allowed with only one data aggregate in each cluster. This option has no effect if two or more aggregates are present.

## Examples

The following example shows the creation of the MetroCluster configuration for a single DR group:

```
clusA::> metrocluster show
  Cluster                Configuration State  Mode
  -----
  Local: clusA           not-configured      -
  Remote: clusB          not-configured      -
clusA::> metrocluster node show
  DR      Configuration  DR
  Group Cluster Node      State      Mirroring Mode
  -----
  -      clusA   clusA-01   ready to configure  -      -
                clusA-02   ready to configure  -      -
                clusA-03   ready to configure  -      -
```

```

clusA-04          ready to configure
-                -
4 entries were displayed.
clusA::> metrocluster configure -node clusA-01
[Job 45] Job succeeded: Configure is successful
clusA::> metrocluster show
Cluster          Configuration State  Mode
-----
Local: clusA    partially-configured  normal
Remote: clusB   partially-configured  normal
clusA::> metrocluster node show
DR              Configuration  DR
Group Cluster Node  State          Mirroring Mode
-----
-   clusA   clusA-03   ready to configure  -   -
           clusA-04   ready to configure  -   -
1   clusA   clusA-01   configured          enabled  normal
           clusA-02   configured          enabled  normal
   clusB   clusB-01   configured          enabled  normal
           clusB-02   configured          enabled  normal
6 entries were displayed.

```

The following example shows the creation of the MetroCluster configuration for all DR groups:

```

clusA::> metrocluster show
Cluster          Configuration State  Mode
-----
Local: clusA    not-configured      -
Remote: clusB   not-configured      -
clusA::> metrocluster node show
DR              Configuration  DR
Group Cluster Node  State          Mirroring Mode
-----
-   clusA   clusA-01   ready to configure  -   -
           clusA-02   ready to configure  -   -
           clusA-03   ready to configure  -   -
           clusA-04   ready to configure  -   -
4 entries were displayed.
clusA::> metrocluster configure
[Job 45] Job succeeded: Configure is successful
clusA::> metrocluster show
Cluster          Configuration State  Mode
-----
Local: clusA    configured          normal

```

```

Remote: clusB
clusA::> metrocluster node show
DR
Group Cluster Node      Configuration State  DR Mirroring Mode
-----
1   clusA  clusA-01      configured enabled normal
      clusA  clusA-02      configured enabled normal
      clusB  clusB-01      configured enabled normal
      clusB  clusB-02      configured enabled normal
2   clusA  clusA-03      configured enabled normal
      clusA  clusA-04      configured enabled normal
      clusB  clusB-03      configured enabled normal
      clusB  clusB-04      configured enabled normal

8 entries were displayed.

```

# metrocluster heal

Heal DR data aggregates and DR root aggregates

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **metrocluster heal** command heals DR data aggregates and DR root aggregates in preparation for a DR switchback. You must issue this command twice to complete the two phases of the healing process: first to heal the aggregates by resynchronizing the mirrored plexes and then to heal the root aggregates by switching them back to the disaster site. The DR partner nodes must be powered off and remote disk shelves must be powered on before running this command.

## Parameters

### **-phase {aggregates|root-aggregates} - MetroCluster Healing Phase**

This parameter specifies the healing phase. The first phase, **aggregates**, heals aggregates by resynchronizing mirrored plexes. The second phase, **root-aggregates**, heals the root aggregates of partner nodes. Healing root aggregates switches them back to the disaster site, allowing the site to boot up.

### **[-override-vetoes <true>] - Override All Soft Vetoes**

This optional parameter overrides almost all heal operation soft vetoes. If this optional parameter

is set to true, the system overrides subsystem soft vetoes that might prevent the heal operation. Hard vetoes cannot be overridden and can still prevent the switchback operation.

## Examples

The following example performs the healing of both the aggregates and root aggregates:

```
cluster1::> metrocluster heal -phase aggregates
           [Job 136] Job succeeded: Heal Aggregates is successful
cluster1::> metrocluster heal -phase root-aggregates
           [Job 137] Job succeeded: Heal Root Aggregates is successful
```

# metrocluster modify

Modify MetroCluster configuration options

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **metrocluster modify** command modifies MetroCluster parameters for nodes in the MetroCluster configuration.

## Parameters

{ **-auto-switchover-failure-domain** <MetroCluster AUSO Failure Domain> - Cluster Level AUSO

### Option

This parameter specifies the configuration of automatic switchover. Modifying **auto-switchover-failure-domain** is not supported on a MetroCluster over IP configuration.

The parameter values are:

- **auso-on-cluster-disaster** - triggers an unplanned switchover if all nodes in a DR cluster are down.
- **auso-on-dr-group-disaster** - triggers an unplanned switchover if both nodes of a DR group are down.
- **auso-disabled** - automatic switchover is disabled.

On a MetroCluster over IP configuration, **auto-switchover-failure-domain** is set to **auso-disabled** ; otherwise, it is set to **auso-on-cluster-disaster** .

A change to the parameter affects only the local cluster where the **metrocluster modify** command is used.

## **| -enable-unmirrored-aggr-deployment {true|false} - Enable or Disable Unmirrored Aggregate Deployment**

Enable or disable unmirrored aggregates deployment

## **| [-allow-auto-forced-switchover {true|false}] - Allow Automatic Forced Switchover**

This parameter is used to enable automatic forced switchover on node failures. The **allow-auto-forced-switchover** parameter is only supported on a MetroCluster over IP configuration.

All nodes in a MetroCluster configuration must have this option enabled to enable automatic forced switchover on failure.

## **| -node-name {<nodename>|local} - Node to Change the Option On }**

This parameter is used to specify the node in the cluster for which the parameter needs to be modified.

## **[-automatic-switchover-onfailure <true>] - Node Level AUSO Option }**

This parameter is used to enable automatic switchover on node failures. The **automatic-switchover-onfailure** parameter is not supported on a MetroCluster over IP configuration.

All nodes in a MetroCluster configuration must have this option enabled to enable automatic switchover on failure.

## Examples

The following example shows the output of Metrocluster modification done on a node:

```
clusA::*> metrocluster modify -node-name clusA-01 -node-object-limit on
[Job 168] Job succeeded: Modify is successful
clusA::*> metrocluster modify -node-name clusA-01 -automatic-switchover-onfailure
false
[Job 308] Job succeeded: Modify is successful
clusA::*> metrocluster modify -auto-switchover-failure-domain auso-on-cluster-disaster
[Job 308] Job succeeded: Modify is successful
```

## metrocluster remove-dr-group

Remove a DR group from a MetroCluster configuration with multiple DR groups

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **metrocluster remove-dr-group** command removes a DR group from a MetroCluster configuration with multiple DR groups.

The command removes the local nodes in the identified DR group from the MetroCluster

configuration. The command must be repeated on the partner cluster to remove the remote nodes in the identified DR group.

A DR group cannot be removed when the MetroCluster configuration has only a single DR group. Two or more DR groups must be configured. The command does not allow a user from unconfiguring the entire MetroCluster. Contact Fujitsu support personnel to unconfigure the entire MetroCluster.

The following preparation steps must be completed on the local and partner clusters before removing a DR group.

- Move all data volumes to another DR group.
- Move all MDV\_CRS metadata volumes to another DR group.
- Delete all MDV\_aud metadata volumes that may exist in the DR group to be removed.
- Delete all data aggregates in the DR group to be removed. Root aggregates are not deleted.
- Migrate all data LIFs to home nodes in another DR group.
- Migrate the cluster management LIF to a home node in another DR group. Node management and inter-cluster LIFs are not migrated.
- Transfer epsilon to a node in another DR group.

The command is vetoed if the preparation steps are not completed on the local and partner clusters.

## Parameters

**-dr-group-id <integer> - DR Group ID**

This parameter identifies the DR group to be removed.

## Examples

```
cluster_A::*> metrocluster remove-dr-group -dr-group-id 1
```

```
Warning: Nodes in the DR group that are removed from the MetroCluster
         configuration will lose their disaster recovery protection.
Local nodes "node_A1, node_A2" will be removed from the Metro-
         Cluster configuration. You must repeat the operation on the
         partner cluster "cluster_B" to remove the remote nodes in the
         DR group.
```

```
Do you want to continue? {y|n}: y
```

```
Info: The following preparation steps must be completed on the local and
      partner clusters before removing a DR group.
```

1. Move all data volumes to another DR group.
2. Move all MDV\_CRS metadata volumes to another DR group.
3. Delete all MDV\_aud metadata volumes that may exist in the DR group to be removed.
4. Delete all data aggregates in the DR group to be removed. Root

```

aggregates are not deleted.
5. Migrate all data LIFs to home nodes in another DR group.
6. Migrate the cluster management LIF to a home node in another DR
group. Node management and inter-cluster LIFs are not migrated.
7. Transfer epsilon to a node in another DR group.
The command is vetoed if the preparation steps are not completed
on the local and partner clusters.
Do you want to continue? {y|n}: y
[Job 80] Job succeeded: Remove DR Group is successful.

```

## metrocluster show

Display MetroCluster configuration information

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **metrocluster show** command displays configuration information for the pair of clusters configured in MetroCluster.

This command displays the following details about the local cluster and the DR partner cluster:

- Configuration State: This field specifies the configuration state of the cluster.
- Mode: This field specifies the operational mode of the cluster.
- AUSO Failure Domain: This field specifies the AUSO failure domain of the cluster.

### Parameters

**[-periodic-check-status ]**

If this option is used the MetroCluster periodic check status is displayed.

### Examples

The following example shows the output of the command before MetroCluster configuration is done:

```

clusA::> metrocluster show
Cluster                Entry Name            State
-----
Local: clusA
  Configuration State  not-configured
  Mode                 -
  AUSO Failure Domain  -
Remote: clusB

```

```

Configuration State not-configured
Mode -
AUSO Failure Domain -

```

The following example shows the output of the command after MetroCluster configuration is done only for some DR groups:

```

clusA::> metrocluster show
Cluster                Entry Name            State
-----
Local: clusA
  Configuration State  partially-configured
  Mode -
  AUSO Failure Domain -
Remote: clusB
  Configuration State  partially-configured
  Mode -
  AUSO Failure Domain -

```

The following example shows the output of the command after MetroCluster configuration is done:

```

clusA::> metrocluster show
Cluster                Entry Name            State
-----
Local: clusA
  Configuration State  configured
  Mode normal
  AUSO Failure Domain  auso-on-cluster-disaster
Remote: clusB
  Configuration State  configured
  Mode normal
  AUSO Failure Domain  auso-on-cluster-disaster

```

The following example shows the output of the command in switchover mode:

```

clusA::> metrocluster show
Cluster                Entry Name            State
-----
Local: clusA
  Configuration State  configured
  Mode switchover
  AUSO Failure Domain  auso-on-cluster-disaster
Remote: clusB
  Configuration State  not-reachable
  Mode -
  AUSO Failure Domain  not-reachable

```

The following example shows the output of the command when `-periodic-check-status` option is used:

```
clusA::> metrocluster show -periodic-check-status
Cluster                Periodic Check Enabled
-----
Local: clusA           true
Remote: clusB          true
```

## metrocluster switchback

Switch back storage and client access

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The `'metrocluster switchback'` command initiates the switchback of storage and client access from nodes in the DR site to their home nodes. The home nodes and storage shelves must be powered on and reachable by nodes in the DR site. The `<<metrocluster-heal,metrocluster heal>>'-phase''_aggregates_''` and `<<metrocluster-heal,metrocluster heal>>'-phase''_root-aggregates_''` commands must have successfully completed before running the `'metrocluster switchback'` command.

### Parameters

#### `[-f, -override-vetoes <true>]` - Override All Soft Vetoes

This optional parameter overrides all switchback operation soft vetoes. If this optional parameter is used, the system overrides subsystem soft vetoes that might prevent the switchback operation. Hard vetoes cannot be overridden and can still prevent the switchover operation.

#### `[-simulate <true>]` - Simulate Switchback

If this optional parameter is used, the system runs a simulation of the switchback operation to make sure all the prerequisites for the operation are met. This parameter cannot be used with switchback operations performed for switching back left-behind aggregates or for retrying a partially successful switchback.

### Examples

The following is an example of how to start the switchback operation.

```
clusA::> metrocluster switchback
```

## Related Links

- [metrocluster heal](#)

# metrocluster switchover

Switch over storage and client access

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `metrocluster switchover` command initiates the switchover of storage and client access from the source cluster to the disaster recovery (DR) site. This command is to be used after a disaster that renders all the nodes in the source cluster unreachable and powered off. It can also be used for negotiated switchover when the outage of the source cluster is anticipated as in cases such as disaster recovery testing or a site going offline for maintenance. If a switchover operation previously failed on certain nodes on the DR site then issuing the command retries the operation on all of those nodes.

## Parameters

### { [-simulate <true>] - Simulate Negotiated Switchover

If this optional parameter is used, the system runs a simulation of the negotiated switchover operation to make sure all the prerequisites for the operation are met. This parameter cannot be used with switchover with the `-forced-on-disaster` parameter.

### { [-controller-replacement <true>] - Indicate Controller Replacement

If this optional parameter is used, the nodes in the DR site will be halted during the negotiated switchover operation, to facilitate controller replacement.

### [ [-forced-on-disaster <true>] - Force Switchover on Disaster

This optional parameter forces a switchover on disaster. This parameter should be used if all the nodes on the disaster stricken site are powered off and unreachable. In the absence of this parameter, the command attempts to perform a negotiated switchover operation.

### [-force-nvfail-all <true>] - Sets in-nvfailed-state on All Volumes

If this parameter is used, the switchover command will set the `in-nvfailed-state` parameter to true for all volumes being switched over and will set the `-dr-force-nvfail` parameter to true for any volumes that do not already have it enabled. This parameter has no effect when performing a negotiated switchover.

### [-retry-failed-nodes <Node name>, ...] - Nodes to Switchover }

This optional parameter takes the list of nodes that previously failed the switchover operation and

it retries the switchover operation on each of the nodes. This parameter is applicable only for a switchover with the **-forced-on-disaster** parameter.

### **[-override-vetoes <true>] - Override All Soft Vetoes**

This optional parameter overrides all switchover operation soft vetoes. If this parameter is used, the system overrides all subsystem soft vetoes that might prevent the switchover operation. Hard vetoes cannot be overridden and can still prevent the switchover operation.

## Examples

When a disaster strikes one site, the **metrocluster switchover** command is issued on the disaster recovery site as follows:

```
cluster1::> metrocluster switchover -forced-on-disaster true
```

```
Warning: MetroCluster switchover is a Disaster Recovery operation that could  
cause some data loss. The cluster on the other site must either be  
prevented from serving data or be simply powered off (nodes and disk  
shelves)
```

```
The following nodes ( cluster1-01 cluster1-02 ) will participate in  
the switchover operation
```

```
Do you want to continue? {y|n}: y
```

```
Queued job. Use 'metrocluster operation show' to check status of the DR operation.
```

```
cluster1::> metrocluster operation show
```

```
Operation: switchover
```

```
State: successful
```

```
Start time: 10/3/2013 22:11:47
```

```
End time: 10/3/2013 22:11:53
```

```
Errors: -
```

# metrocluster check disable-periodic-check

## Disable Periodic Check

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **metrocluster check disable-periodic-check** command disables the periodic checking of the MetroCluster configuration.

After this command is run, the MetroCluster Check job will be prevented from periodically checking the configuration for errors.

## Parameters

## Examples

```
clusA::> metrocluster check disable-periodic-check
```

# metrocluster check enable-periodic-check

Enable Periodic Check

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **metrocluster check enable-periodic-check** command enables the periodic checking of the MetroCluster configuration.

After this command is run, the MetroCluster Check job will be able to run in the background and periodically check the configuration for errors.

## Parameters

## Examples

```
clusA::> metrocluster check enable-periodic-check
```

# metrocluster check run

Check the MetroCluster setup

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **metrocluster check run** command performs checks on the MetroCluster configuration and reports configuration errors if any.

To run this command, at least one DR group needs to be configured. The command checks the following parts of the configuration:

Node Configuration:

- **node-reachable:** This check verifies that the node is reachable.
- **metrocluster-ready:** This check verifies that the node is ready for MetroCluster configuration.

- `local-ha-partner`: This check verifies that the HA partner node is in the same cluster.
- `ha-mirroring-on`: This check verifies that HA mirroring for the node is configured.
- `symmetric-ha-relationship`: This check verifies that the relationship between the node and its HA partner is symmetric.
- `remote-dr-partner`: This check verifies that the DR partner node is in the remote cluster.
- `dr-mirroring-on`: This check verifies that DR mirroring for the node is configured.
- `symmetric-dr-relationship`: This check verifies that the relationship between the node and its DR partner is symmetric.
- `remote-dr-auxiliary-partner`: This check verifies that the DR auxiliary partner node is in the remote cluster.
- `symmetric-dr-auxiliary-relationship`: This check verifies that the relationship between the node and its DR auxiliary partner is symmetric.
- `storage-failover-enabled`: This check verifies that storage failover is enabled.
- `has-intercluster-lif`: This check verifies that the node has an intercluster LIF.
- `node-object-limit`: This check verifies that the node object limit option for the node is turned on.

#### Aggregate Configuration:

- `mirroring-status`: This check verifies that the aggregate is mirrored.
- `disk-pool-allocation`: This check verifies that the disks belonging to this aggregate have been correctly allocated to the right pools.

At the end of the check the command displays a summary of the results. This summary output can be viewed again by running `metrocluster check show`. If any of the rows in this output show any warnings more details can be viewed by running the `metrocluster check show` command for that component.

## Parameters

### `[-skip-dr-simulation {true|false}]` - Skip the DR Readiness Checks

If this optional parameter is set to true, the switchover and switchback simulations are not run.

## Examples

The following example shows the execution of the command when there are no warnings:

```
clusA::> metrocluster check run

                Last Checked On: 4/9/2014 20:11:46
Component          Result
-----
nodes              ok
clusters          ok
```

```
lifs                ok
config-replication ok
aggregates         ok
```

5 entries were displayed.

Command completed. Use the "metrocluster check show -instance" command or sub-commands in "metrocluster check" directory for detailed results.

The following example shows the execution of the command when there are some warnings:

```
clusA::> metrocluster check run
Last Checked On: 4/9/2014 20:11:46
Component          Result
```

```
-----
nodes              warning
clusters           ok
lifs               ok
config-replication ok
aggregates         ok
```

5 entries were displayed.

Command completed. Use the "metrocluster check show -instance" command or sub-commands in "metrocluster check" directory for detailed results.

## Related Links

- [metrocluster check show](#)

# metrocluster check show

Show the results of the last instance of MetroCluster check

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **metrocluster check show** command displays the results of the [metrocluster check run](#) command.

This command displays the high-level verification results for each of the components. If there are any errors for a component, running the show command for that component (for example [metrocluster check node show](#) or [metrocluster check aggregate show](#) ) will display more information about the warning.

Please note that this command does not run the checks but only displays the results of checks. To look at the latest results, run the [metrocluster check run](#) command and then run this command.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[ [-instance ] ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-timestamp <MM/DD/YYYY HH:MM:SS>] - Time of Check**

This is the time at which the metrocluster check run command was last run in this cluster and these results were produced. If this parameter is specified, only rows with this timestamp will be displayed.

**[-component <MetroCluster Check Components>] - Name of the Component**

This is the name of the component. If this parameter is specified, only rows with this component will be displayed.

**[-result {ok|warning|not-run|not-applicable}] - Result of the Check**

This is the result of the check for the component. If this parameter is specified, only rows with this result will be displayed.

**[-additional-info <text>] - Additional Information/Recovery Steps**

This is the additional info for the verification for this component. This field will have detailed information about the warning and recovery steps. If this parameter is specified, only rows with this additional info will be displayed.

## Examples

The following example shows the execution of the command when there are no warnings:

```
clusA::> metrocluster check show
Checked On: 4/9/2014 20:11:46
t          Result
-----
nodes          ok
clusters       ok
lifs           ok
config-replication ok
aggregates     ok
connections    ok
s were displayed.
```

The following example shows the execution of the command when there are some warnings:

```
clusA::> metrocluster check show
Checked On: 4/9/2014 20:11:46
t          Result
-----
nodes      warning
clusters   ok
lifs       ok
config-replication ok
aggregates ok
connections ok
6 entries were displayed.
```

The following example shows the execution of the command with -instance option:

```

- [metrocluster check aggregate show](#)

# metrocluster check aggregate show

Show results of MetroCluster check for aggregates

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **metrocluster check aggregate show** command displays the results of aggregate checks performed by the **metrocluster check run** command.

The command verifies the following aspects of the configuration of all aggregates in MetroCluster:

- **mirroring-status:** This check verifies that the aggregate is mirrored.
- **disk-pool-allocation:** This check verifies that the disks belonging to this aggregate have been correctly allocated to the right pools.

Additional information about the warnings (if any) and recovery steps can be viewed by running the command with the **-instance** option.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[ -node <Node name> ] - Node Name**

This is the name of the node for which the check was run. If this parameter is specified, only rows with this node will be displayed.

**[ -aggregate <aggregate name> ] - Name of the Aggregate**

This is the name of the aggregate for which the check was run. If this parameter is specified, only rows with this aggregate will be displayed.

**[ -check <MetroCluster Aggregate Check> ] - Type of Check**

This is the type of the check performed. If this parameter is specified, only rows with this check will be displayed.

**[ -cluster <cluster name> ] - Name of Cluster**

This is the name of the cluster the node belongs to. If this parameter is specified, only rows with this cluster will be displayed.

**[-result {ok|warning|not-run|not-applicable}] - Result of the Check**

This is the result of the check. If this parameter is specified, only rows with this result will be displayed.

**[-additional-info <text>,...] - Additional Information/Recovery Steps**

This is additional information about the check. This field has more information and recovery steps for the warning. If this parameter is specified, only rows with this additional info will be displayed.

## Examples

The following example shows the execution of the command in a MetroCluster configuration with two nodes per cluster:

```
clusA::> metrocluster check aggregate show
```

```
Last Checked On: 4/9/2014 20:11:46
```

Node	Aggregate	Check	Result
clusA-01	a1_required_data_aggr	mirroring-status	ok
		disk-pool-allocation	ok
	aggr0_a1	mirroring-status	ok
		disk-pool-allocation	ok
clusA-02	a2_required_data_aggr	mirroring-status	ok
		disk-pool-allocation	ok
	aggr0_a2	mirroring-status	ok
		disk-pool-allocation	ok
clusB-01	b1_required_data_aggr	mirroring-status	ok
		disk-pool-allocation	ok
	aggr0_b1	mirroring-status	ok
		disk-pool-allocation	ok
clusB-02	aggr0_b2	mirroring-status	ok
		disk-pool-allocation	ok
	b2_required_data_aggr	mirroring-status	ok
		disk-pool-allocation	ok

```
16 entries were displayed.
```

The following example shows the execution of the command with -instance option:

```
clusA::> metrocluster check aggregate show -instance
```

```
Node Name: clusA-01
    Name of the Aggregate: a1_required_data_aggr_1
    Type of Check: mirroring-status
    Name of Cluster: clusA
    Result of the Check: ok
Additional Information/Recovery Steps: -

## Related Links

- [metrocluster check run](#)

# metrocluster check cluster show

Show results of MetroCluster check for the cluster components

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **metrocluster check cluster show** command displays the results of cluster checks performed by the [metrocluster check run](#) command.

The command displays the results of the following cluster configuration checks:

- **negotiated-switchover-ready:** This check verifies that the cluster is ready for a negotiated switchover operation.
- **switchback-ready:** This check verifies that the cluster is ready for a switchback operation.
- **job-schedules:** This check verifies that the job schedules between the local and remote clusters are consistent.

- **licenses:** This check verifies that the licenses between the local and remote clusters are consistent.
- **periodic-check-enabled:** This check verifies that the periodic MetroCluster Check Job is enabled.
- **onboard-key-management:** This check verifies that the Onboard Key Management hierarchies are consistent.
- **external-key-management:** This check verifies that the External Key Management configurations are consistent.

Additional information about the warnings (if any) and recovery steps can be viewed by running the command with the **-instance** parameter.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-check {negotiated-switchover-ready|switchback-ready|job-schedules|licenses|periodic-check-enabled|onboard-key-management|external-key-management}] - Type of Check**

This is the type of the check performed. If this parameter is specified, only rows with this check will be displayed.

**[-cluster <cluster name>] - Cluster Name**

This is the name of the cluster the check results apply to. If this parameter is specified, only rows matching the specified cluster will be displayed.

**[-result {ok|warning|not-run|not-applicable}] - Result of the Check**

This is the result of the check. If this parameter is specified, only rows with this result will be displayed.

**[-additional-info <text>] - Additional Information/Recovery Steps**

This is additional information about the check. This field has more information and recovery steps for the warning. If this parameter is specified, only rows with this additional info will be displayed.

## Examples

The following example shows the execution of the command in a MetroCluster configuration:

```
clusA::> metrocluster check cluster show
```

```
Last Checked On: 11/29/2018 17:15:00
```

Cluster	Check	Result
clusA	negotiated-switchover-ready	not-applicable
	switchback-ready	not-applicable
	job-schedules	ok
	licenses	ok
	periodic-check-enabled	ok
	onboard-key-management	ok
	external-key-management	ok
clusB	negotiated-switchover-ready	not-applicable
	switchback-ready	not-applicable
	job-schedules	ok
	licenses	ok
	periodic-check-enabled	ok
	onboard-key-management	ok
	external-key-management	ok

14 entries were displayed.

The following example shows the execution of the command with the **-instance** parameter:

```
clusA::> metrocluster check cluster show -instance
Type of Check: negotiated-switchover-ready
      Cluster Name: clusA
      Result of the Check: not-applicable
Additional Information/Recovery Steps: Disaster recovery readiness checks are not
performed as part of periodic metrocluster check. To run these checks, use the
"metrocluster check run" command.
Type of Check: switchback-ready
      Cluster Name: clusA
      Result of the Check: not-applicable
Additional Information/Recovery Steps: Disaster recovery readiness checks are not
performed as part of periodic metrocluster check. To run these checks, use the
"metrocluster check run" command.
Type of Check: job-schedules
      Cluster Name: clusA
      Result of the Check: ok
Additional Information/Recovery Steps:
Type of Check: licenses
      Cluster Name: clusA
      Result of the Check: ok
Additional Information/Recovery Steps:

- [metrocluster check run](#)

# metrocluster check config-replication show-aggregate-eligibility

**Availability:** This command is available to *cluster* administrators at the *admin*

privilege level.

## Description

The `metrocluster check config-replication show-aggregate-eligibility` command displays the MetroCluster configuration replication aggregate eligibility.

## Parameters

`{[-fields <fieldname>,...]}`

If you specify the `-fields <fieldname>`, ... parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

`[-instance ]}`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-aggregate <aggregate name>] - Aggregate`

This is the aggregate name. If this parameter is specified, only rows with this aggregate will be displayed.

`[-hosted-configuration-replication-volumes <volume name>,...]` - **Currently Hosted Configuration Replication Volumes**

This is the list of the configuration replication volumes hosted on this aggregate. If this parameter is specified, only rows with these configuration replication volumes will be displayed.

`[-is-eligible-to-host-additional-volumes {true|false}]` - **Eligibility to Host Another Configuration Replication Volume**

This is the eligibility of the aggregate to host additional configuration replication volumes. If this parameter is specified, only rows with this eligibility will be displayed.

`[-comment <text>]` - **Comment for Eligibility Status**

This is a comment regarding the eligibility of the aggregate to host configuration replication volumes. If this parameter is specified, only rows with this comment will be displayed.

## Examples

The following example shows the execution of the command in a MetroCluster configuration with thirteen aggregates in the cluster:

```
clusA::metrocluster check config-replication> show-aggregate-eligibility
Aggregate      Hosted Config Replication Vols      Eligible to
Host Addl Vols Comments
-----

## metrocluster check config-replication show-capture-status

Display MetroCluster capture status information

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

The **metrocluster check config-replication show-capture-status** command indicates whether or not a configuration change that would prevent a negotiated switchover is currently being captured for replication.

### Examples

The following example shows the execution of the command in a MetroCluster configuration when capture is not in progress:

```

cluster1::*> metrocluster check config-replication show-capture-status
Is Capture in Progress: false

```

# metrocluster check config-replication show

Display MetroCluster config-replication status information

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **metrocluster check config-replication show** command displays the results of MetroCluster configuration replication.

The command verifies the following aspects of MetroCluster configuration replication :

- **Enabled:** Verifies that MetroCluster configuration replication is enabled on the cluster.
- **Running:** Verifies that MetroCluster configuration replication is running on the cluster.
- **Remote Heartbeat:** Verifies that the MetroCluster configuration replication heartbeat with the remote cluster is healthy.
- **Last Heartbeat Sent:** Prints the timestamp of the last MetroCluster configuration replication heartbeat sent to the remote cluster.
- **Last Heartbeat Received:** Prints the timestamp of the last MetroCluster configuration replication heartbeat received from the remote cluster.
- **Storage Status:** Verifies that MetroCluster configuration replication storage is healthy.
- **Storage In Use:** Prints the location of MetroCluster configuration replication storage.
- **Storage Remarks:** Prints the underlying root cause for non healthy MetroCluster configuration storage.
- **Vserver Streams:** Verifies that MetroCluster configuration replication Vserver streams are healthy.
- **Cluster Streams:** Verifies that MetroCluster configuration replication Cluster streams are healthy.

Additional information about the warnings (if any) and recovery steps can be viewed by running the command with the `-instance` option.

## Parameters

**[`-instance` ]**

If you specify the `-instance` parameter, the command displays detailed information about all fields.

## Examples

The following example shows the output of **metrocluster check config-replication show** :

```
clusA::metrocluster check config-replication> show
```

```

                Enabled: true
                Running: true
                Remote Heartbeat: ok
                Last Heartbeat Sent: 12/12/2013 14:24:59

                Storage Status: ok
                Storage In Use: Cluster-wide Volume:
MDV_CRS_1bc7134a5ddf11e3b63f123478563412_A
                Storage Remarks: -
                Vserver Streams: ok
                Cluster Streams: ok

```

## metrocluster check connection show

Display the check results of connections for nodes in a MetroCluster over IP configuration

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The `metrocluster check connection show` command displays the check results of connections for nodes in a MetroCluster over IP configuration.

### Parameters

`{ [-fields <fieldname>,...]`

If you specify the `-fields <fieldname>,...` parameter, the command displays only the fields that you specify.

`[-instance ]}`

If this parameter is specified, the command displays detailed information about all entries.

`[-dr-group-id <integer>] - DR Group ID`

If this parameter is specified, the command displays information for the matching DR group.

`[-cluster-uuid <UUID>] - Cluster UUID`

If this parameter is specified, the command displays information for the matching cluster specified by uuid.

`[-cluster <Cluster name>] - Cluster Name`

If this parameter is specified, the command displays information for the matching cluster.

`[-node-uuid <UUID>] - Node UUID`

If this parameter is specified, the command displays information for the matching node specified by uuid.

**[-node <text>] - Node Name**

If this parameter is specified, the command displays information for the matching nodes.

**[-home-port {<netport>|<ifgrp>}] - Home Port**

If this parameter is specified, the command displays information for the matching home-port.

**[-relationship-type <Roles of MetroCluster Nodes>] - Relationship Role Type**

If this parameter is specified, the command displays information for the matching relationship-type.

**[-source-address <IP Address>] - Source Network Address**

If this parameter is specified, the command displays information for the matching source address.

**[-destination-address <IP Address>] - Destination Network Address**

If this parameter is specified, the command displays information for the matching destination address.

**[-partner-cluster-uuid <UUID>] - Partner Cluster UUID**

If this parameter is specified, the command displays information for the matching partner-cluster-uuid.

**[-partner-node-uuid <UUID>] - Partner Node UUID**

If this parameter is specified, the command displays information for the matching partner-node-uuid.

**[-partner-node <text>] - Partner Node Name**

If this parameter is specified, the command displays information for the matching partner-node.

**[-partner-type <text>] - Partner Relationship Type**

If this parameter is specified, the command displays information for the matching partner-type.

**[-config-state <text>] - Configuration State**

If this parameter is specified, the command displays information for the matching config-state.

**[-config-error-info <text>] - Configuration Error Information**

If this parameter is specified, the command displays information for the matching config-error-info.

**[-check-result {ok|warning|not-run|not-applicable}] - Check Connection Result**

If this parameter is specified, the command displays information for the matching check-result.

**[-check-ping-error-info <text>] - Check Connection Ping Error Info**

If this parameter is specified, the command displays information for the matching check-ping-error-info.

**[-check-mtu-size-error-info <text>] - Check Connection MTU Size Error Info**

If this parameter is specified, the command displays information for the matching check-mtu-size-error-info.

**[-check-storage-error-info <text>] - Check Connection Storage Error Info**

If this parameter is specified, the command displays information for the matching check-storage-error-info.

**Examples**

The following example shows the output of the **metrocluster check connection show** command:

```
clusA::> metrocluster check connection show

## metrocluster check lif repair-placement

Repair LIF placement for the sync-source Vserver LIFs in the destination cluster

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `metrocluster check lif repair-placement` command reruns LIF placement for those LIFs displayed by the `metrocluster check lif show` command. This command is expected to be run after the admin manually rectifies the LIF placement failures displayed in the `metrocluster check lif show` command output. The command is successful if the LIF placement rerun does not encounter any LIF placement failure. This is to be confirmed by subsequent running of the `metrocluster check lif show` command.

## Parameters

### `-vserver <Vserver Name> - sync-source Vserver Name`

This is the name of the sync source Vserver that has LIF placement failures as reported by the `metrocluster check lif show` command. This input ensures that the command is run on the specified Vserver.

### `[-lif <lif-name>] - Logical Interface Name`

This is the Logical Interface name that belongs to the sync source Vserver that has a LIF placement failure in the destination cluster as reported by the `metrocluster check lif show` command. This input ensures that the command is run on the specified LIF only.

## Examples

The following example shows the execution of the command with a sync source Vserver and a LIF specified:

```
clusA::> metrocluster check lif repair-placement -vserver vs1.example.com -lif fcplif1
Command completed. Run the "metrocluster check lif show" command for results.

clusA::> metrocluster check lif repair-placement -vserver vs1.example.com -lif
iscsilif1
Command completed. Run the "metrocluster check lif show" command for results.
```

The following example shows the execution of the command with only a sync-source Vserver specified:

```
clusA::> metrocluster check lif repair-placement -vserver vs1.example.com

Command completed. Run the "metrocluster check lif show" command for results.

clusA::>
```

## Related Links

- [metrocluster check lif show](#)

# metrocluster check lif show

Show results of MetroCluster check results for the data LIFs

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `metrocluster check lif show` command displays the LIF placement failures in the MetroCluster configuration.

The command verifies the following aspects of the LIF placements of all the data LIFs in Metrocluster:

- `lif-placed-on-dr-node`: This check verifies that the LIF is placed on DR partner node.
- `port-selection`: This check verifies that the LIF is placed on correct port.

The LIF placement failures are mostly fabric/network connectivity issues that require manual intervention. Once the connectivity issues are resolved manually, the admin is expected to run `metrocluster check lif repair-placement` command to resolve the LIF placement issues for the sync source Vserver.

Additional information about the warnings (if any) and recovery steps can be viewed by running the command with the `-instance` option.

## Parameters

`{ [-fields <fieldname>,...]`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

`[-instance ]}`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-cluster <cluster name>] - Name of the Cluster`

This is the name of the cluster the LIF belongs to. If this parameter is specified, only rows with this cluster will be displayed.

`[-vserver <text>] - Name of the Vserver`

This is the name of the Vserver in the MetroCluster configuration

**[-lif <lif-name>] - Name of the Lif**

This is the name of the LIF.

**[-check <MetroCluster LIF placement Check>] - Description**

This is the type of the check performed. If this parameter is specified, only rows with this check will be displayed.

**[-result {ok|warning|not-run|not-applicable}] - Result of the Check**

This is the result of the check performed. If this parameter is specified, only rows with this result will be displayed.

**[-additional-info <text>] - Additional Information/Recovery Steps**

This is additional information about the check. This field has more information and recovery steps for the warning. If this parameter is specified, only rows with this additional info will be displayed.

## Examples

The following example shows the execution of the command in a MetroCluster configuration with two nodes per cluster:

```
clusA::>metrocluster check lif show
```

Cluster	Vserver	LIF	Check	Result
ClusA	vs1	a_data1	lif-placed-on-dr-node	ok
			port-selection	ok
ClusA	vs2-mc	a_data1_inet6	lif-placed-on-dr-node	ok
			port-selection	ok
		b_data1	lif-placed-on-dr-node	ok
			port-selection	warning
ClusB	vs1-mc	a_data1	lif-placed-on-dr-node	warning
			port-selection	ok
		a_data1_inet6	lif-placed-on-dr-node	warning
			port-selection	ok
ClusB	vs2	b_data1	lif-placed-on-dr-node	ok
			port-selection	ok
		b_data1_inet6	lif-placed-on-dr-node	ok
			port-selection	ok

16 entries were displayed.

# metrocluster check node show

Show results of MetroCluster check for nodes

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `metrocluster check node show` command displays the results of node checks performed by the [metrocluster check run](#) command.

The command displays the results of the following node configuration checks:

- `node-reachable`: This check verifies that the node is reachable.
- `metrocluster-ready`: This check verifies that the node is ready for MetroCluster configuration.
- `local-ha-partner`: This check verifies that the HA partner node is in the same cluster.
- `ha-mirroring-on`: This check verifies that HA mirroring for the node is configured.
- `ha-mirroring-op-state`: This check verifies that the HA mirroring operation is online.
- `symmetric-ha-relationship`: This check verifies that the relationship between the node and its HA partner is symmetric.
- `remote-dr-partner`: This check verifies that the DR partner node is in the remote cluster.
- `dr-mirroring-on`: This check verifies that DR mirroring for the node is configured.
- `dr-mirroring-op-state`: This check verifies that the DR mirroring operation is online.
- `symmetric-dr-relationship`: This check verifies that the relationship between the node and its DR partner is symmetric.
- `remote-dr-auxiliary-partner`: This check verifies that the DR auxiliary partner node is in the remote cluster.
- `symmetric-dr-auxiliary-relationship`: This check verifies that the relationship between the node and its DR auxiliary partner is symmetric.
- `storage-failover-enabled`: This check verifies that storage failover is enabled.
- `has-intercluster-lif`: This check verifies that the node has an intercluster LIF.
- `node-object-limit`: This check verifies that the node object limit option for the node is turned on.
- `automatic-uso`: This check verifies that the automatic USO option for the node is enabled.

Additional information about the warnings (if any) and recovery steps can be viewed by running the command with the `-instance` parameter.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[ [-instance ] ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-node <Node name>] - Node Name**

This is the name of the node for which the check was run. If this parameter is specified, only rows with this node will be displayed.

**[-check <MetroCluster Node Check>] - Type of Check**

This is the type of the check performed. If this parameter is specified, only rows with this check will be displayed.

**[-cluster <Cluster name>] - Cluster Name**

This is the name of the cluster the node belongs to. If this parameter is specified, only rows with this cluster will be displayed.

**[-result {ok|warning|not-run|not-applicable}] - Result of the Check**

This is the result of the check. If this parameter is specified, only rows with this result will be displayed.

**[-additional-info <text>] - Additional Information/Recovery Steps**

This is additional information about the check. This field has more information and recovery steps for the warning. If this parameter is specified, only rows with this additional info will be displayed.

## Examples

The following example shows the execution of the command in a MetroCluster configuration with two nodes per cluster:

```
clusA::> metrocluster check node show
```

```
Last Checked On: 9/12/2016 13:47:00
```

Node	Check	Result

# metrocluster check volume show

Show results of the MetroCluster check for volumes

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **metrocluster check volume show** command displays the results of volume checks performed by the [metrocluster check run](#) command.

The command displays the results of the following volume configuration checks:

- **unmirrored-flexgroups:** This check looks for flexgroups residing on unmirrored aggregates.

- **mixed-flexgroups:** This check looks for flexgroups residing on a mix of mirrored and unmirrored aggregates.

Additional information about the warnings, if any, and recovery steps can be viewed by running the command with the **-instance** parameter.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ [-instance ] ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-vserver <vserver name>] - Vserver Name**

This is the name of the vserver that contains the volume that the check results apply to. If this parameter is specified, only rows matching the specified cluster will be displayed.

**[-volume <volume name>] - Volume Name**

This is the name of the volume that the check results apply to. If this parameter is specified, only rows matching the specified volume will be displayed.

**[-check <MetroCluster Volume Check>] - Type of Check**

This is the type of the check performed. If this parameter is specified, only rows with this check will be displayed.

**[-result {ok|warning|not-run|not-applicable}] - Result of the Check**

This is the result of the check. If this parameter is specified, only rows with this result will be displayed.

**[-additional-info <text>, ...] - Additional Information/Recovery Steps**

This is additional information about the check. This field has more information and recovery steps for the warning. If this parameter is specified, only rows with this additional info will be displayed.

## Examples

The following example shows the execution of the command in a MetroCluster configuration:

```
clusA::*> metrocluster check volume show
```

```
Last Checked On: 7/25/2018 10:04:07
```

Vserver	Volume	Check	Result
vs1	unMirr		

```

vs2                vs2UnMirrA                unmirrored-volumes    warning
vs2                vs2UnMirrA                unmirrored-volumes    warning
2 entries were displayed.

clusA::*> metrocluster check volume show -instance
Vserver Name: vs1
                Volume Name: unMirr
                Type of Check: unmirrored-volumes
                Result of the Check: warning
Additional Information/Recovery Steps: FlexGroup "unMirr" resides on unmirrored
aggregates. Parts of the FlexGroup may not be available after an un-planned
switchover.
Vserver Name: vs2
                Volume Name: vs2UnMirrA
                Type of Check: unmirrored-volumes
                Result of the Check: warning
Additional Information/Recovery Steps: FlexGroup "vs2UnMirrA" resides on unmirrored
aggregates. Parts of the FlexGroup may not be available after an un-planned
switchover.
2 entries were displayed.

# metrocluster config-replication cluster-storage-configuration modify

Modify MetroCluster storage configuration information

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **metrocluster config-replication cluster-storage-configuration modify** command modifies the configuration of storage used for configuration replication.

## Parameters

**[-disallowed-aggregates <aggregate name>, ...] - Disallowed Aggregates**

Use this parameter to set the list of storage aggregates that are not available to host storage for configuration replication.

## Examples

The following example disallows two aggregates named **aggr1** and **aggr2** :

```
cluster1::*> metrocluster config-replication cluster-storage-configuration modify
-disallowed-aggregates aggr1,aggr2
```

# metrocluster config-replication cluster-storage-configuration show

Display MetroCluster storage configuration information

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **metrocluster config-replication cluster-storage-configuration show** command shows details of the configuration of the storage used for configuration replication.

The information displayed is the following:

- Disallowed Aggregates - The list of storage aggregates that are configured as not allowed to host storage areas.
- Auto-Repair - Displays **true** if the automatic repair of storage areas used by configuration replication is enabled.
- Auto-Recreate - Displays **true** if the automatic recreation of storage volumes used by configuration replication is enabled.
- Use Mirrored Aggregate - Displays **true** if storage areas for configuration replication are to be hosted on a mirrored aggregate.

## Examples

The following is an example of the **metrocluster config-replication cluster-storage-configuration show** command:

```
cluster1::*> metrocluster config-replication cluster-storage-configuration show
Disallowed Aggregates: -
    Auto-Repair: true
    Auto-Recreate: true
Use Mirrored Aggregate: true
```

# metrocluster config-replication resync-status show

Display MetroCluster Configuration Resynchronization Status

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `metrocluster config-replication resync-status show` command displays the state of the configuration synchronization operation between the two clusters in the MetroCluster configuration.

This command displays the following details about the local cluster and the peer cluster:

- **Source:** This is the source side whose configuration is being replicated to the destination side.
- **Destination:** This is the destination side where the configuration is being replicated to from the source side.
- **State:** This is the state of the synchronization operation.
- **% Complete:** This is completion percentage of the operation.

## Examples

The following example shows the output of the command when synchronization is in progress:

```
clusterA::> metrocluster config-replication resync-status show
  Source           Destination           State           % Complete
  -----
  clusterA         clusterB             complete        -
  clusterB         clusterA             complete        -
```

The following example shows the output of the command when synchronization from clusB to clusA is in progress:

```
clusA::> metrocluster config-replication resync-status show
  Source           Destination           State           % Complete
  -----
  clusterA         clusterB             complete        -
  clusterB         clusterA             messaging       95
```

# metrocluster configuration-settings show-status

Display the configuration settings status for a MetroCluster setup

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **metrocluster configuration-settings show-status** command displays the configuration settings status for nodes in a MetroCluster setup. If a DR group has not been created, then status for nodes in the local cluster only are displayed.

## Parameters

**{ [-fields <fieldname>,...]**

If you specify the **-fields <fieldname>,...** parameter, the command displays only the fields that you specify.

**[-instance ]}**

If this parameter is specified, the command displays detailed information about all entries.

**[-cluster-uuid <UUID>] - Cluster UUID**

If this parameter is specified, the command displays detailed information about all nodes in the cluster matching the specified cluster-uuid.

**[-cluster <Cluster name>] - Cluster Name**

If this parameter is specified, the command displays detailed information about all the nodes in the specified cluster.

**[-node <text>] - Node Name**

If this parameter is specified, the command displays information for the matching nodes.

**[-configuration-status <text>] - Configuration Settings Status**

If this parameter is specified, the command displays detailed information about all nodes with the specified configuration status.

**[-config-error-info <text>] - Configuration Error Information**

If this parameter is specified, the command displays detailed information about all nodes with the specified configuration error information.

## Examples

The following example shows the display of MetroCluster setup status:

Nodes do not have a valid platform-specific personality value (equivalent to HAOSC parameter on non-Apollo platforms) for a MetroCluster setup.

```
clusA::> metrocluster configuration-settings show-status
```

Cluster	Node	Configuration Settings Status
clusA	A1	not a MetroCluster setup
	A2	not a MetroCluster setup

2 entries were displayed.

MetroCluster setup uses FC links rather than IP link:

```
clusA::> metrocluster configuration-settings show-status
```

Cluster	Node	Configuration Settings Status
clusA	A1	not applicable for FC and SAS
	A2	not applicable for FC and SAS

2 entries were displayed.

Output of the command when MetroCluster setup uses IP links and before `"metrocluster configuration-settings dr-group create"` command is run:

```
clusA::> metrocluster configuration-settings show-status
```

Cluster	Node	Configuration Settings Status
clusA	A1	ready for DR group create
	A2	ready for DR group create

2 entries were displayed.

Output of the command after `"metrocluster configuration-settings dr-group create"` command is run:

```
clusA::> metrocluster configuration-settings show-status
```

Cluster	Node	Configuration Settings Status
clusA	A1	ready for interface create
	A2	ready for interface create
clusB	B1	ready for interface create
	B2	ready for interface create

4 entries were displayed.

Output of the command after `"metrocluster configuration-settings interface create"` command is run for every node:

```
clusA::> metrocluster configuration-settings show-status
```

Cluster	Node	Configuration Settings Status
clusA	A1	ready for next interface create
	A2	ready for connection connect
clusB	B1	ready for connection connect
	B2	ready for connection connect

4 entries were displayed.

Output of the command after `"metrocluster configuration-settings connection connect"` command is run:

```
clusA::> metrocluster configuration-settings show-status
```

Cluster	Node	Configuration Settings Status
clusA	A1	completed
	A2	completed
clusB	B1	completed
	B2	completed

4 entries were displayed.

Output of the command after ` "metrocluster configuration-settings connection connect" ` command is run and there are connection errors:

```
clusA::> metrocluster configuration-settings show-status
```

Cluster	Node	Configuration Settings Status
clusA	A1	connection error
	A2	completed
clusB	B1	connection error
	B2	completed

4 entries were displayed.

## metrocluster configuration-settings calibration measure

Measure latency and bandwidth values

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

The **metrocluster configuration-settings calibration measure** command measures the bandwidth and latency between local and remote nodes in a MetroCluster over IP configuration.

This command should not be run when the MetroCluster configuration is under a heavy load. Bandwidth measurements will attempt to fully saturate network connections to the remote cluster and may disrupt the quality of service.

### Examples

The following example shows the output for the calibration measure command in MetroCluster over IP configurations:

```
clusA::*> metrocluster configuration-settings calibration measure
Warning: This operation will attempt to fully saturate the network connection to
the remote cluster for measuring bandwidth. This may disrupt
performance and should not be run when MetroCluster is under heavy
```

```

load. Do you want to continue? {y|n}: y
Measuring latency and bandwidth between node "A1" (10.140.113.214) and node "B1"
(10.140.113.26) over port "e0f".
Measuring latency and bandwidth between node "A1" (10.140.113.215) and node "B1"
(10.140.113.27) over port "e0g".
Measuring latency and bandwidth between node "A2" (10.140.113.216) and node "B2"
(10.140.113.25) over port "e0f".
Measuring latency and bandwidth between node "A2" (10.140.113.217) and node "B2"
(10.140.113.28) over port "e0g".
Measurements complete. Use the "metrocluster configuration-settings calibration
show" command to display the results.

```

## metrocluster configuration-settings calibration show

Display the calibration measurements for local nodes in MetroCluster over IP configuration

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The `metrocluster configuration-settings calibration show` command shows the bandwidth and latency between local and remote nodes in a MetroCluster over IP configuration.

### Parameters

`{ [-fields <fieldname>, ... ] }`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

`[ [-instance ] ] }`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-calibration-id <integer>] - Calibration ID`

This field specifies Calibration ID.

`[-subnet <IP Address>] - IP Subnet`

This field specifies subnet.

`[-node-uuid <UUID>] - Node UUID`

This field specifies UUID of the node.

**[-home-port {<netport>|<ifgrp>}] - Home Port**

This field specifies name of the port used to measure latency and bandwidth.

**[-node {<nodename>|local}] - Node Name**

This field specifies name of the node.

**[-collection-time <MM/DD/YYYY HH:MM:SS>] - Collection Time of Sample**

This field specifies collection time of sample.

**[-source-address <IP Address>] - Source Network Address**

This field specifies IP address of the port on the node.

**[-destination-address <IP Address>] - Destination Network Address**

This field specifies IP address of the port on the partner node.

**[-latency <double>] - Latency in ms**

This field specifies latency in ms.

**[-bandwidth <double>] - Bandwidth in Mb/s**

This field specifies bandwidth in Mb/s.

## Examples

The following example shows the output for the calibration show command in MetroCluster over IP configurations:

```
clusA::*> metrocluster configuration-settings calibration show
          Home Latency Bandwidth
ID Subnet      Node   Port (ms)  (Mb/s)    Collection Time
-----
1  172.21.96.0  A1
          e0f  0.341    764       8/6/2019 16:20:07
          e0g  0.311    629       8/6/2019 16:20:22
          A2
          e0f  0.307    1265      8/6/2019 16:20:36
          e0g  0.307    1063      8/6/2019 16:20:50
4 entries were displayed.
```

# metrocluster configuration-settings connection check

Check the network connections between partner nodes

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `metrocluster configuration-settings connection check` command checks the settings of a MetroCluster over IP configuration.

This command is used for MetroCluster configurations that are connected through IP links.

## Examples

The following example shows the output for the check command in MetroCluster over IP configurations:

```
clusA::*> metrocluster configuration-settings connection check
[Job 68] Job succeeded: Connect is successful.
```

```
Begin connection check.
Start checking the partner cluster.
  Check partner cluster: PASS.
Start checking the configuration settings.
  Check configuration settings: PASS.
Start pinging the network endpoints from cluster "clusA".
  Ping network endpoints: PASS.
Start pinging the network endpoints from cluster "clusB".
  Ping network endpoints: PASS.
Start checking the network MTU sizes from cluster "clusA".
  Check network MTU sizes: PASS.
Start checking the network MTU sizes from cluster "clusB".
  Check network MTU sizes: PASS.

  Check storage daemons: PASS.
End of connection check.
```

# metrocluster configuration-settings connection connect

Configure the network connections between partner nodes

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **metrocluster configuration-settings connection connect** command configures the connections that mirror NV logs and access remote storage between partner nodes in a MetroCluster setup.

This command is used for MetroCluster setups that are connected through IP links. MetroCluster setups that are connected through FC links will configure the FC connections automatically.

The **metrocluster configuration-settings** commands are run in the following order to set up MetroCluster:

- [metrocluster configuration-settings dr-group create](#) ,
- [metrocluster configuration-settings interface create](#) ,
- **metrocluster configuration-settings connection connect** .

Before this command is run

- The DR groups must have been configured. Run the [metrocluster configuration-settings dr-group show](#) command to verify that every node is partnered in a DR group.
- The network logical interfaces must have been configured on every node. Use the [metrocluster configuration-settings interface show](#) command to verify that every node has network logical interfaces configured to mirror NV logs and access remote storage.

After this command completes successfully, every node will:

- Have NV log mirroring configured and mirroring disabled. NV log mirroring will be enabled by the [metrocluster configure](#) command.
- Have access to remote storage. Use the [storage disk show -pool Pool1](#) command to view the remote disks that are hosted on DR partner nodes.

The DR groups and network logical interfaces that were configured by the **metrocluster configuration-settings** commands cannot be deleted after the connections have been configured. The [metrocluster configuration-settings connection disconnect](#) command must be run to remove the connections before the DR groups and network logical interfaces can be deleted.

## Parameters

## Examples

The following example shows configuration of connections in a MetroCluster over IP setup:

```
clusA::> metrocluster configuration-settings connection connect
[Job 269] Job succeeded: Connect is successful.
clusA::> metrocluster configuration-settings connection show
```

DR Group	Cluster	Node	Source Network Address	Destination Network Address	Partner Type	Config State

# metrocluster configuration-settings connection disconnect

Tear down the network connections between partner nodes

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `metrocluster configuration-settings connection disconnect` command removes the connections between nodes in a DR group that are used to mirror NV logs and access remote storage.

This command cannot be run if a node in the DR group has remote disks assigned to the node. The assigned ownership of remote disks can be removed by running the [storage disk removeowner](#) command.

The `metrocluster configuration-settings` commands are run in the following order to remove

MetroCluster over IP configuration:

- `metrocluster configuration-settings connection disconnect` ,
- `metrocluster configuration-settings interface delete` ,
- `metrocluster configuration-settings dr-group delete` .

## Parameters

`-dr-group-id <integer>` - DR Group ID

This parameter identifies the DR group to be disconnected.

## Examples

The following example illustrates removal of connections in a four-node MetroCluster setup:

```
clusA::> metrocluster configuration-settings connection disconnect -dr-group-id 1
[Job 270] Job succeeded: Disconnect is successful.
```

```
clusA::> metrocluster configuration-settings show-status
```

# metrocluster configuration-settings connection show

Display the connections between partner nodes in a MetroCluster setup

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `metrocluster configuration-settings connection show` command displays the connection configuration information between the nodes in a MetroCluster setup.

## Parameters

`{ [-fields <fieldname>,...]`

If you specify the `-fields <fieldname>,...` parameter, the command displays only the fields that you specify.

`[-instance ]}`

If this parameter is specified, the command displays detailed information about all entries.

`[-dr-group-id <integer>] - DR Group ID`

If this parameter is specified, the command displays information for the matching DR group.

`[-cluster-uuid <UUID>] - Cluster UUID`

If this parameter is specified, the command displays information for the matching cluster specified by uuid.

`[-cluster <Cluster name>] - Cluster Name`

If this parameter is specified, the command displays information for the matching cluster.

`[-node-uuid <UUID>] - Node UUID`

If this parameter is specified, the command displays information for the matching node specified by uuid.

`[-node <text>] - Node Name`

If this parameter is specified, the command displays information for the matching nodes.

`[-home-port {<netport>|<ifgrp>}] - Home Port`

If this parameter is specified, the command displays information for the matching home-port.

`[-relationship-type <Roles of MetroCluster Nodes>] - Relationship Role Type`

If this parameter is specified, the command displays information for the matching relationship-type.

**[-source-address <IP Address>] - Source Network Address**

If this parameter is specified, the command displays information for the matching source address.

**[-destination-address <IP Address>] - Destination Network Address**

If this parameter is specified, the command displays information for the matching destination address.

**[-partner-cluster-uuid <UUID>] - Partner Cluster UUID**

If this parameter is specified, the command displays information for the matching partner-cluster-uuid.

**[-partner-node-uuid <UUID>] - Partner Node UUID**

If this parameter is specified, the command displays information for the matching partner-node-uuid.

**[-partner-node <text>] - Partner Node Name**

If this parameter is specified, the command displays information for the matching partner-node.

**[-partner-type <text>] - Partner Relationship Type**

If this parameter is specified, the command displays information for the matching partner-type.

**[-config-state <text>] - Configuration State**

If this parameter is specified, the command displays information for the matching config-state.

**[-config-error-info <text>] - Configuration Error Information**

If this parameter is specified, the command displays information for the matching config-error-info.

## Examples

The following example shows the output of `metrocluster configuration-settings connection connect` command:

Output of the command before the connections are established using the `<<metrocluster-configuration-settings-connection-connect,metrocluster configuration-settings connection connect>>` command:

```
clusA::> metrocluster configuration-settings connection show

## Related Links

- [metrocluster configuration-settings connection connect](#)

# metrocluster configuration-settings dr-group create

Create a DR group in a MetroCluster over IP setup

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **metrocluster configuration-settings dr-group create** command partners the nodes that will comprise a DR group in a MetroCluster setup.

This command is used for MetroCluster setups that are connected through IP links. MetroCluster setups that are connected through FC links will configure DR groups automatically and do not require the **metrocluster configuration-settings** commands.

The **metrocluster configuration-settings** commands are run in the following order to set up MetroCluster:

- **metrocluster configuration-settings dr-group create** ,
- [metrocluster configuration-settings interface create](#) ,
- [metrocluster configuration-settings connection connect](#) .

Before running this command, cluster peering must be configured between the local and partner clusters. Run the [cluster peer show](#) command to verify that peering is available between the local and partner clusters.

This command configures a local node and a remote node as DR partner nodes. The command also configures the HA partner of the local node and the HA partner of the remote node as the other DR partner nodes in the DR group.

## Parameters

**-partner-cluster <Cluster name> - Partner Cluster Name**

Use this parameter to specify the name of the partner cluster.

**-local-node {<nodename>|local} - Local Node Name**

Use this parameter to specify the name of a node in the local cluster.

**-remote-node <text> - Remote Node Name**

Use this parameter to specify the name of a node in the partner cluster that is to be the DR partner of the specified local node.

## Examples

The following example shows the creation of the MetroCluster DR group:

```
clusA::> metrocluster configuration-settings dr-group create -partner-cluster clusB
-local-node A1 -remote-node B1
[Job 268] Job succeeded: DR Group Create is successful.
```

```
clusA::> metrocluster configuration-settings dr-group show
DR Group ID Cluster Node DR Partner Node
-----
1 clusA
A1 B1
A2 B2
clusB
B2 A2
B1 A1
```

# metrocluster configuration-settings dr-group delete

Delete a DR group in a MetroCluster over IP setup

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `metrocluster configuration-settings dr-group delete` command deletes a DR group and its node partnerships that were configured using the `metrocluster configuration-settings dr-group create` command.

This command cannot be run if the `metrocluster configuration-settings interface create` command has configured a network logical interface on a network port provisioned for MetroCluster. The `metrocluster configuration-settings interface delete` command must then be run to delete the network logical interfaces on every node in the DR group.

The `metrocluster configuration-settings` commands are run in the following order to remove the MetroCluster over IP configuration:

- `metrocluster configuration-settings connection disconnect` ,
- `metrocluster configuration-settings interface delete` ,
- `metrocluster configuration-settings dr-group delete` .

## Parameters

`-dr-group-id <integer>` - Dr group Id

This parameter identifies the DR group to be deleted.

## Examples

The following example shows the deletion of the MetroCluster DR group:

```
clusA::> metrocluster configuration-settings dr-group delete -dr-group-id 1
```

```
Warning: This command deletes the existing DR group relationship. Are you sure  
you want to proceed ? {y|n}: y  
[Job 279] Job succeeded: DR Group Delete is successful.
```

```
clusA::> metrocluster configuration-settings dr-group show  
No DR groups exist.
```

```
clusA::> metrocluster configuration-settings show-status
```

Cluster	Node	Configuration Settings Status
clusA	A1	ready for DR group create
	A2	ready for DR group create
clusB	B1	ready for DR group create
	B2	ready for DR group create

4 entries were displayed.

# metrocluster configuration-settings dr-group show

Display the DR groups in a MetroCluster over IP setup

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `metrocluster configuration-settings dr-group show` command displays the DR groups and their nodes in the MetroCluster over IP setup.

## Parameters

`{ [-fields <fieldname>, ... ] }`

If you specify the `-fields <fieldname>, ...` parameter, the command displays only the fields that you specify.

`[ -instance ] }`

If this parameter is specified, the command displays detailed information about all entries.

`[ -dr-group-id <integer> ] - DR Group ID`

If this parameter is specified, the command displays information for the matching DR group.

`[ -cluster-uuid <UUID> ] - Cluster UUID`

If this parameter is specified, the command displays information for the matching cluster uuid.

**[-cluster <Cluster name>] - Cluster Name**

If this parameter is specified, the command displays information for the specified cluster.

**[-node-uuid <UUID>] - Node UUID**

If this parameter is specified, the command displays information for the matching nodes uuid.

**[-node <text>] - Node Name**

If this parameter is specified, the command displays information for the matching nodes.

**[-dr-partner-node-uuid <UUID>] - DR Partner Node UUID**

If this parameter is specified, the command displays information for the matching DR partner node uuid.

**[-dr-partner-node <text>] - DR Partner Node Name**

If this parameter is specified, the command displays information for the matching DR partner nodes.

## Examples

The following example illustrates the display of DR group configuration in a four-node MetroCluster setup:

```
clusA::> metrocluster configuration-settings dr-group show
DR Group ID Cluster                Node                DR Partner Node
-----
1          clusA
           A1          B1
           A2          B2
           clusB
           B2          A2
           B1          A1
4 entries were displayed.
```

# metrocluster configuration-settings interface create

Create a MetroCluster interface

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `metrocluster configuration-settings interface create` command configures the network logical interfaces that will be used on a node in a MetroCluster setup to mirror NV logs and access remote storage.

This command is used for MetroCluster setups that are connected through IP links. MetroCluster setups that are connected through FC links do not require the user to provision network logical interfaces to mirror NV logs and access remote storage.

The `metrocluster configuration-settings` commands are run in the following order to set up MetroCluster:

- `metrocluster configuration-settings dr-group create` ,
- `metrocluster configuration-settings interface create` ,
- `metrocluster configuration-settings connection connect` .

Before running this command , the node's DR group must be configured using the `metrocluster configuration-settings dr-group create` command. Run the `metrocluster configuration-settings dr-group show` command to verify that the node's DR group has been configured.

## Parameters

### `-cluster-name <Cluster name>` - Cluster Name

Use this parameter to specify the name of the local or partner cluster.

### `-home-node <text>` - Home Node

Use this parameter to specify the home node in the cluster which hosts the interface.

### `-home-port {<netport>|<ifgrp>}` - Home Port

Use this parameter to specify the home port provisioned for MetroCluster.

### `-address <IP Address>` - Network Address

Use this parameter to specify the network address to be assigned to the home port.

### `-netmask <Contiguous IP Mask>` - Netmask

Use this parameter to specify the network mask to be assigned to the interface.

### `[-gateway <IP Address>]` - Gateway

Use this parameter to specify the gateway to be assigned for the routed network.

### `[-vlan-id <integer>]` - Virtual LAN ID

Use this parameter to specify the VLAN id.

## Examples

This example shows configuring logical interface on MetroCluster IP capable port:

```
clusA::> metrocluster configuration-settings interface create -cluster-name clusA
-home-node A1 -home-port e0f -address 10.140.113.214 -netmask 255.255.192.0
[Job 281] Job succeeded: Interface Create is successful.

clusA::> metrocluster configuration-settings interface show
```

```
DR
Group Cluster Node      Network Address Netmask      Gateway      Config
-----
1      clusA A1
      Home Port: e0f
      10.140.113.214 255.255.192.0 -
```

completed

Output after configuring all the interfaces:

clusA::> metrocluster configuration-settings interface show

```
DR
Group Cluster Node      Network Address Netmask      Gateway      Config
-----
1      clusA A1

# metrocluster configuration-settings interface delete

Delete a MetroCluster interface

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `metrocluster configuration-settings interface delete` command deletes the network logical interface that was configured on a network port provisioned for MetroCluster.

This command cannot be run if the [metrocluster configuration-settings connection connect](#) command has set up the connections between the nodes in a DR group. The [metrocluster configuration-settings connection disconnect](#) command must then be run to remove the connections.

The `metrocluster configuration-settings` commands are run in the following order to remove the MetroCluster over IP configuration:

- [metrocluster configuration-settings connection disconnect](#) ,
- `metrocluster configuration-settings interface delete` ,
- [metrocluster configuration-settings dr-group delete](#) .

## Parameters

**-cluster-name <Cluster name> - Cluster Name**

Use this parameter to specify the name of the local or partner cluster.

**-home-node <text> - Home Node**

Use this parameter to specify the home node in the cluster which hosts the interface.

**-home-port {<netport>|<ifgrp>} - Home Port**

Use this parameter to specify the home port provisioned for MetroCluster.

## Examples

The following example shows the deletion of interface in a MetroCluster setup:

```
clusA::> metrocluster configuration-settings interface delete -cluster-name clusA
-home-node A1 -home-port e0f
[Job 271] Job succeeded: Interface Delete is successful.
```

```
clusA::> metrocluster configuration-settings interface show

# metrocluster configuration-settings interface show

Display the network logical interfaces provisioned for MetroCluster

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **metrocluster configuration-settings interface show** command displays the network logical interfaces that were provisioned for MetroCluster.

## Parameters

**{ [-fields <fieldname>,...]**

If you specify the **-fields <fieldname>,...** parameter, the command displays only the fields that you specify.

**l [-instance ]}**

If this parameter is specified, the command displays detailed information about all entries.

**[-dr-group-id <integer>] - DR Group ID**

If this parameter is specified, the command displays information for the matching DR group.

**[-cluster-uuid <UUID>] - Cluster UUID**

If this parameter is specified, the command displays information for the matching cluster specified by uuid.

**[-cluster <Cluster name>] - Cluster Name**

If this parameter is specified, the command displays information for the matching cluster..

**[-node-uuid <UUID>] - Node UUID**

If this parameter is specified, the command displays information for the matching nodes uuid.

**[-node <text>] - Node Name**

If this parameter is specified, the command displays information for the matching nodes.

**[-home-port {<netport>|<ifgrp>}] - Home Port**

If this parameter is specified, all interfaces with home-port set to this value are displayed.

**[-address <IP Address>] - Network Address**

If this parameter is specified, the command displays information for the matching network address.

**[-netmask <Contiguous IP Mask>] - Netmask**

If this parameter is specified, all interfaces with netmask set to this value are displayed.

**[-gateway <IP Address>] - Gateway**

If this parameter is specified, all interfaces with gateway set to this value are displayed.

**[-config-state <text>] - Configuration State**

If this parameter is specified, all interfaces with this field set to the specified value are displayed.

**[-config-error-info <text>] - Configuration Error Information**

If this parameter is specified, all interfaces with this field set to the specified value are displayed.

**[-vlan-id <integer>] - Virtual LAN ID**

If this parameter is specified, all interfaces with vlan-id set to this value are displayed.

## Examples

The following example illustrates display of logical interfaces configured in a four-node MetroCluster setup:

```
clusA::> metrocluster configuration-settings interface show
DR
Group Cluster Node   Network Address Netmask      Gateway      Config
-----
1      clusA A1

## metrocluster configuration-settings mediator add

Configure the network connections between the Mediator and MetroCluster nodes

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The `metrocluster configuration-settings mediator add` command configures the connection between the mediator and all the nodes in a MetroCluster configuration.

Before this command is run MetroCluster should be configured on all the clusters.

Mediator username and password are required to successfully add the mediator.

After this command completes successfully, every node will:

- Have a connection with the mediator.
- The mediator disks will be assigned to the nodes in the MetroCluster configuration.
- AUSO will be enabled.

### Parameters

**-mediator-address <IP Address> - Mediator IP Address**

Specifies the IP address of the mediator to which the nodes in the MetroCluster configuration will be connected.

### Examples

The following example connects the nodes to the mediator in a MetroCluster

configuration over IP setup:

```
clusA::> metrocluster configuration-settings mediator add -mediator-address
10.234.133.115
    Adding mediator and enabling Automatic Unplanned Switchover. It might take a
few minutes to complete.
    Please enter the username for the mediator: mediatoradmin
    Please enter the password for the mediator:
    Confirm the mediator password:
    Creating mediator mailboxes...
    Setting up connections to mediator from all nodes in the clusters...
    Setting mediator mailbox from all nodes in the cluster...
    Enabling Automatic Unplanned Switchover for all nodes in the cluster...
    Successfully added mediator.
```

## metrocluster configuration-settings mediator remove

Tear down connections between the Mediator and MetroCluster nodes

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The `metrocluster configuration-settings mediator remove` command removes the connection between the mediator and all the nodes in a MetroCluster configuration.

Mediator username and password are required to successfully remove the mediator.

### Parameters

**[-dr-group-id <integer>] - DR Group Id**

Specifies the Disaster Recovery Group Identifier for which the mediator connections need to be removed.

### Examples

The following example removes the connections between the nodes and the mediator in a MetroCluster configuration over IP setup:

```
clusA::> metrocluster configuration-settings mediator remove
    Removing the mediator and disabling Automatic Unplanned Switchover. It may take
```

```
a few minutes to complete.  
Please enter the username for the mediator: mediatoradmin  
Please enter the password for the mediator:  
Confirm the mediator password:  
Disabling Automatic Unplanned Switchover for all nodes in the cluster...  
Removing mediator mailboxes...  
Performing final cleanup...  
Successfully removed the mediator.
```

# metrocluster configuration-settings mediator show

Display the nodes connected to the mediator

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `metrocluster configuration-settings mediator show` command displays the connection status of the nodes with the Mediator in a MetroCluster configuration.

## Parameters

`{ [-fields <fieldname>, ... ] }`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

`[ -instance ] }`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[ -mediator-address <IP Address> ] - Mediator IP Address`

Specifies the IP address of the mediator to which the nodes in the MetroCluster configuration are connected.

`[ -port <integer> ] - Mediator port number`

Specifies the port of the mediator to which the nodes in the MetroCluster configuration are connected.

`[ -node {<nodename>|local} ] - Node Name`

Specifies the nodes in the MetroCluster configuration which are connected to the mediator.

`[ -reachable {true|false} ] - Connection Status of the Mediator`

Specifies the connection status of the nodes with the mediator in the MetroCluster configuration.

**[-configured {true|false}] - Mediator Configuration Status**

Specifies the configuration status of the nodes with the mediator in the MetroCluster configuration.

## Examples

The following example shows the mediator connection status in a MetroCluster configuration over IP setup:

```
cluster1_node_01::*> metrocluster configuration-settings mediator show
  Mediator IP      Port      Node                               Configuration Connection
  Status          Status
-----
10.234.217.168
                31784    cluster1_node_01                   true           true
                cluster1_node_02                   true           true
                cluster2_node_01                   true           true
                cluster2_node_02                   true           true
```

# metrocluster interconnect adapter modify

Modify MetroCluster interconnect adapter settings

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **metrocluster interconnect adapter modify** command enables you to modify settings of the MetroCluster interconnect adapter.

## Parameters

**-node {<nodename>|local} - Node Name**

This parameter specifies the node name.

**-is-ood-enabled {true|false} - Is Out-of-Order Delivery Enabled?**

This parameter specifies the out-of-order delivery setting on the adapter.

## Examples

The following example enables out-of-order delivery for the port 'fcvi\_device\_0' on the node 'clusA-01':

```
clusA::*> metrocluster interconnect adapter modify -node clusA-01 -adapter-port-name
fcvi_device_0 -is-ood-enabled true
```

# metrocluster interconnect adapter show

Display MetroCluster interconnect adapter information

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **metrocluster interconnect adapter show** command displays interconnect adapter information for the nodes in a MetroCluster configuration.

This command displays the following details about the local node and the HA partner node:

- Node: This field specifies the name of the node in the cluster.
- Adapter Name: This field specifies the name of the interconnect adapter.
- Adapter Type: This field specifies the type of the interconnect adapter.
- Link Status: This field specifies the physical link status of the interconnect adapter.
- Is OOD Enabled: This field specifies the out-of-order delivery status of the interconnect adapter.
- IP Address: This field specifies the IP address assigned to the interconnect adapter.
- Port Number: This field specifies the port number of the interconnect adapter.

## Parameters

**{ [-fields <fieldname>, ... ]**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ [-connectivity ]**

Displays the connectivity information from all the interconnect adapters to the connected nodes.

**[ [-switch ]**

Displays details of switches connected to all the interconnect adapters.

**[ [-connectivity-hidden ]**

Displays additional connectivity information (IP address, Area ID, Port ID) from all the interconnect adapters to the connected nodes.

**[ [-instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node Name**

Displays information only about the interconnect adapters that are hosted by the specified node.

**[-adapter <text>] - Adapter**

Displays information only about the interconnect adapters that match the specified name.

**[-port-name <text>] - Port Name**

Displays information only about the interconnect adapters that host the specified port name.

**[-type <text>] - Adapter Type**

Displays information only about the interconnect adapters that match the specified adapter type.

**[-physical-status <text>] - Physical Status**

Displays information only about the interconnect adapters that match the specified physical status.

**[-wwn <text>] - Adapter Port World Wide Name**

Displays information only about the interconnect adapters that match the specified world wide name.

**[-address <text>] - IP Address**

Displays information only about the interconnect adapters that match the specified IP address.

**[-firmware-version <text>] - Firmware Version**

Displays information only about the interconnect adapters that match the specified firmware version.

**[-link-speed <text>] - Link Speed**

Displays information only about the interconnect adapters that match the specified link speed.

**[-link-speed-neg-type <text>] - Link Speed Negotiation Type**

Displays information only about the interconnect adapters that match the specified negotiated link speed type.

**[-switch-name <text>] - Switch Name**

Displays information only about the interconnect adapters that are connected to the specified switch.

**[-switch-model <text>] - Switch Model**

Displays information only about the interconnect adapters that are connected to the switch with the specified model.

**[-switch-wwn <text>] - Switch WWName**

Displays information only about the interconnect adapters that are connected to the switch with the specified world wide name.

**[-switch-vendor <text>] - Switch Vendor**

Displays information only about the interconnect adapters that are connected to the switch with the specified vendor.

**[-switch-status <text>] - Switch Status**

Displays information only about the interconnect adapters that are connected to the switch with the specified operational status.

**[-switch-port-number <text>] - Switch Port Number**

Displays information only about the interconnect adapters that are connected to the switch with the specified port number.

**[-switch-port-wwpn <text>] - Switch Port WWPN**

Displays information only about the interconnect adapters that are connected to the switch with the specified word wide port name.

**[-remote-adapter-name-list <text>,...] - Remote Adapter Name List**

Displays information only about the interconnect adapters that are connected to the specified remote adapters.

**[-remote-adapter-wwn-list <text>,...] - Remote Adapter WWName List**

Displays information only about the interconnect adapters that are connected to the remote adapters with the specified world wide names.

**[-remote-adapter-address-list <text>,...] - Remote Adapter IP Address List**

Displays information only about the interconnect adapters that are connected to the remote adapters with the specified IP addresses.

**[-remote-adapter-port-id-list <Hex Integer>,...] - Remote Adapter Port ID List**

Displays information only about the interconnect adapters that are connected to the remote adapters with the specified port IDs.

**[-remote-adapter-domain-id-list <integer>,...] - Remote Adapter Domain ID List**

Displays information only about the interconnect adapters that are connected to the remote adapters with the specified domain IDs.

**[-remote-adapter-area-id-list <integer>,...] - Remote Adapter Area ID List**

Displays information only about the interconnect adapters that are connected to the remote adapters with the specified Area IDs.

**[-remote-partner-system-id-list <integer>,...] - Remote Partner System ID List**

Displays information only about the interconnect adapters that are connected to the remote nodes with the specified System IDs.

**[-remote-partner-name-list {<nodename>|local}] - Remote Partner Name List**

Displays information only about the interconnect adapters that are connected to the specified remote nodes.

**[-is-ood-enabled {true|false}] - Is Out-of-Order Delivery Enabled?**

Displays information only about the interconnect adapters that match the specified out-of-order delivery setting.

**Examples**

The following example shows the output of the command during normal operation (neither cluster is in switchover state):

```
clusA::> metrocluster interconnect adapter show
```

Node	Adapter	Type	Link Status	Is OOD Enabled?	IP Address	Port Number
clusA-01	cxgb3_0	iWARP	Up	false	10.0.1.1	c0a
clusA-01	cxgb3_0	iWARP	Down	false	10.0.2.1	c0b
clusA-01	fcvi_device_0	FC-VI	Up	false	1.0.0.1	1a
clusA-01	fcvi_device_1	FC-VI	Up	false	2.0.0.3	1b
clusA-02	cxgb3_0	iWARP	Up	false	10.0.1.2	c0a
clusA-02	cxgb3_0	iWARP	Down	false	10.0.2.2	c0b
clusA-02	fcvi_device_0	FC-VI	Up	false	1.0.1.1	1a
clusA-02	fcvi_device_1	FC-VI	Up	false	2.0.1.3	1b

The following example shows the output of the command after MetroCluster switchover is performed:

```
clusA::> metrocluster interconnect adapter show
```

Node	Adapter	Type	Link Status	Is OOD Enabled?	IP Address	Port Number
clusA-01	cxgb3_0	iWARP	Up	false	10.0.1.1	c0a
clusA-01	cxgb3_0	iWARP	Down	false	10.0.2.1	c0b
clusA-01	fcvi_device_0	FC-VI	Down	false	1.0.0.1	1a
clusA-01	fcvi_device_1	FC-VI	Down	false	2.0.0.3	1b
clusA-02	cxgb3_0	iWARP	Up	false	10.0.1.2	c0a
clusA-02	cxgb3_0	iWARP	Down	false	10.0.2.2	c0b
clusA-02	fcvi_device_0	FC-VI	Down	false	1.0.1.1	1a
clusA-02	fcvi_device_1	FC-VI	Down	false	2.0.1.3	1b

The following example shows the output of the command with connectivity field during normal operation (neither cluster is in switchover state):

```
clusA::> metrocluster interconnect adapter show -connectivity -node local -type FC-VI
Adapter Name: fcvi_device_0
                WWName: 21:00:00:24:ff:32:01:68
                PortNo: 1a

Remote Adapters:
Adapter Name Partner Node Name World Wide Name          PortId
```

```

-----
fcvi_device_0
      clusA-01          21:00:00:24:ff:32:01:80  65536
fcvi_device_0
      clusB-01          21:00:00:24:ff:32:01:54 131072

      clusA-01          21:00:00:24:ff:32:01:81 196608

```

## metrocluster interconnect mirror show

Display MetroCluster interconnect mirror information

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `metrocluster interconnect mirror show` command displays NVRAM mirror information for the nodes configured in a MetroCluster.

This command displays the following details about the local node and the HA partner node:

- Node: This field specifies the name of the node in the cluster.
- Partner Name: This field specifies the name of the partner node.
- Partner Type: This field specifies the type of the partner.
- Mirror Admin Status: This field specifies the administrative status of the NVRAM mirror between partner nodes.
- Mirror Oper Status: This field specifies the operational status of the NVRAM mirror between partner nodes.
- Adapter: This field specifies the name of the interconnect adapter used for NVRAM mirroring.
- Type: This field specifies the type of the interconnect adapter used for NVRAM mirroring.
- Status: This field specifies the physical status of the interconnect adapter used for NVRAM mirroring.

## Parameters

`{ [-fields <fieldname>, ... ] }`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

`[ -instance ] }`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[ -node {<nodename>|local} ] - Node Name`

If this parameter is specified, mirror details of the specified node are displayed.

`[ -partner-type {HA|DR|AUX} ] - Partner Type`

If this parameter is specified, mirror details of the specified partner type are displayed.

`[ -adapter <text> ] - Adapter`

If this parameter is specified, mirror details of the specified adapter are displayed.

`[ -type <text> ] - Adapter Type`

If this parameter is specified, mirror details of the specified adapter type are displayed.

`[ -status <text> ] - Status`

If this parameter is specified, mirror details of the adapter with the specified status are displayed.

**[-mirror-oper-status {unknown|online|offline}] - Mirror Operational Status**

If this parameter is specified, only mirror details with the specified operational status are displayed.

**[-partner-name <text>] - Partner Name**

If this parameter is specified, mirror details of the specified partner are displayed.

**[-mirror-admin-status {enabled|disabled}] - Mirror Administrative Status**

If this parameter is specified, only mirror details with the specified administrative status are displayed.

## Examples

The following example shows the output of the command during normal operation (neither cluster is in switchover state):

```
clusA::> metrocluster interconnect mirror show
           Mirror  Mirror
           Partner Admin  Oper
Node Partner Name Type  Status  Status  Adapter Type  Status
-----
clusA-01
  clusA-02
           HA      enabled  online
           cxgb3_0 iWARP  Up
           cxgb3_0 iWARP  Up
  clusB-01
           DR      enabled  online
           fcvi_device_0
           FC-VI  Up
           fcvi_device_1
           FC-VI  Up
clusA-02
  clusA-01
           HA      enabled  online
           cxgb3_0 iWARP  Up
           cxgb3_0 iWARP  Up
  clusB-02
           DR      enabled  online
           fcvi_device_0
           FC-VI  Up
           fcvi_device_1
           FC-VI  Up
```

The following example shows the output of the command after MetroCluster switchover is performed:

```

clusA::> metrocluster interconnect mirror show

```

Node	Partner	Partner Name	Partner Type	Mirror Admin Status	Mirror Oper Status	Adapter	Type	Status
-----								
clusA-01								
	clusA-02		HA	enabled	online			
						cxgb3_0	iWARP	Up
						cxgb3_0	iWARP	Up
	clusB-01		DR	disabled	offline			
						fcvi_device_0		
							FC-VI	Up
						fcvi_device_1		
							FC-VI	Up
clusA-02								
	clusA-01		HA	enabled	online			
						cxgb3_0	iWARP	Up
						cxgb3_0	iWARP	Up
	clusB-02		DR	disabled	offline

							FC-VI	Up
						fcvi_device_1		
							FC-VI	Up

## metrocluster interconnect mirror multipath show

Display multipath information

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **metrocluster interconnect mirror multipath show** command displays the NVRAM mirror multipath policy for the nodes configured in a MetroCluster.

This command displays the following details about the local node and the HA partner node:

- Node: This field specifies the name of the node in the cluster.
- Multipath Policy: This field specifies the multipath policy used for NVRAM mirroring.

## Parameters

{[-fields <fieldname>,...]}

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

{[-instance ]}

If you specify the **-instance** parameter, the command displays detailed information about all fields.

[-node {<nodename>|local}] - Node Name

If this parameter is specified, mirror details of the specified node are displayed.

[-multipath-policy {no-mp|static-map|dynamic-map|round-robin}] - Multipath Policy

If this parameter is specified, nodes with the specified multipath policy are displayed.

## Examples

The following example shows the output of the command:

```
clusA::> metrocluster interconnect mirror multipath show
Node           Multipath Policy
-----
clusA-1        static-map
clusA-2        static-map
```

## metrocluster node show

Display MetroCluster node configuration information

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **metrocluster node show** command displays configuration information for the nodes in the MetroCluster configuration.

## Parameters

{[-fields <fieldname>,...]}

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[ -partners ]**

If this option is used the MetroCluster node partnership view will be displayed.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[ -dr-group-id <integer> ] - DR Group ID**

If this parameter is specified, all nodes belonging to the specified DR group are displayed.

**[ -cluster <Cluster name> ] - Cluster Name**

If this parameter is specified, all nodes belonging to the specified cluster are displayed.

**[ -node <Node name> ] - Node Name**

If this parameter is specified, the specified node is displayed.

**[ -ha-partner <Node name> ] - HA Partner Name**

If this parameter is specified, the node with the specified HA partner is displayed.

**[ -dr-cluster <Cluster name> ] - DR Cluster Name**

If this parameter is specified, all nodes belonging to the specified cluster are displayed.

**[ -dr-partner <Node name> ] - DR Partner Name**

If this parameter is specified, the node with the specified DR partner is displayed.

**[ -dr-auxiliary <Node name> ] - DR Auxiliary Name**

If this parameter is specified, the node with the specified DR auxiliary partner is displayed.

**[ -node-uuid <UUID> ] - Node UUID**

If this parameter is specified, the node with the specified Uuid is displayed.

**[ -ha-partner-uuid <UUID> ] - HA Partner UUID**

If this parameter is specified, the nodes with the specified HA partner is displayed.

**[ -dr-partner-uuid <UUID> ] - DR Partner UUID**

If this parameter is specified, the node with the specified DR partner is displayed.

**[ -dr-auxiliary-uuid <UUID> ] - DR Auxiliary UUID**

If this parameter is specified, the node with the specified DR auxiliary partner is displayed.

**[ -node-cluster-uuid <UUID> ] - Node Cluster UUID**

If this parameter is specified, all nodes belonging to the specified cluster are displayed.

**[ -ha-partner-cluster-uuid <UUID> ] - HA Partner Cluster UUID**

If this parameter is specified, all nodes whose HA partner belong to the specified cluster are displayed.

**[-dr-partner-cluster-uuid <UUID>] - DR Partner Cluster UUID**

If this parameter is specified, all nodes whose DR partner belong to the specified cluster are displayed.

**[-dr-auxiliary-cluster-uuid <UUID>] - DR Auxiliary Cluster UUID**

If this parameter is specified, all nodes whose DR auxiliary partner belong to the specified cluster are displayed.

**[-node-systemid <integer>] - Node System ID**

If this parameter is specified, all nodes with the specified system ID are displayed.

**[-ha-partner-systemid <integer>] - HA Partner System ID**

If this parameter is specified, all nodes with an HA partner with the specified system ID are displayed.

**[-dr-partner-systemid <integer>] - DR Partner System ID**

If this parameter is specified, all nodes with a DR partner with the specified system ID are displayed.

**[-dr-auxiliary-systemid <integer>] - DR Auxiliary System ID**

If this parameter is specified, all nodes with a DR auxiliary partner with the specified system ID are displayed.

**[-dr-mirroring-state <text>] - State of DR Mirroring Config**

If this parameter is specified, all nodes with this field set to the specified value are displayed. This field specifies if the NVRAM mirroring to the DR partner is enabled through the [metrocluster configure](#) command. This field needs to be set to "enabled" for the DR mirroring to be active.

**[-configuration-state <text>] - Configuration State of Node**

If this parameter is specified, all nodes with this field set to the specified value are displayed.

**[-additional-configuration-info <text>] - Additional Configuration Info**

If this parameter is specified, all nodes with this field set to the specified value are displayed.

**[-dr-operation-state <text>] - DR Operation State**

If this parameter is specified, all nodes with this field set to the specified value are displayed.

**[-dr-operation-time <integer>] - Time to Complete Operation (secs)**

If this parameter is specified, all nodes with this field set to the specified value are displayed.

**[-node-object-limit {on|off}] - Specifies if the Node Object Limits are Enforced**

If this parameter is specified, all nodes with this field set to the specified value are displayed.

**[-node-ha-partner <text>] - Node and its HA Partner**

If this parameter is specified, all nodes with this field set to the specified value are displayed.

**[-automatic-uso {true|false}] - Automatic USO**

If this parameter is specified, all nodes with this field set to the specified value are displayed.

**[-mccip-node {true|false}] - MCC-IP Node**

If this parameter is specified, all nodes with this field set to the specified value are displayed.

## Examples

The following example shows the output of the command before the MetroCluster configuration is done:

```
clusA::> metrocluster node show
DR
Group Cluster Node      Configuration State      DR
Mirroring Mode
-----
-   clusA  clusA-01      ready to configure
-   -      -             -           -
-   -      clusA-02      ready to configure
-   -      -             -           -
-   -      clusA-03      ready to configure
-   -      -             -           -
-   -      clusA-04      ready to configure
-   -      -             -           -

4 entries were displayed.
clusA::> metrocluster node show -partners
Node (HA Partner) DR Partner (DR Auxiliary)
-----
Cluster:
clusA -
clusA-01 (-) - (-)
clusA-02 (-) - (-)
clusA-03 (-) - (-)
clusA-04 (-) - (-)

4 entries were displayed.
```

The following example shows the output of the command when some DR groups in the MetroCluster configuration are not yet configured:

```
clusA::> metrocluster node show
DR
Group Cluster Node      Configuration State      DR
Mirroring Mode
-----
-   clusA  clusA-03      ready to configure
-   -      -             -           -
-   -      clusA-04      ready to configure
-   -      -             -           -
1   clusA  clusA-01      configured  enabled    normal
-   -      clusA-02      configured  enabled    normal
```

```

        clusB  clusB-01      configured  enabled  normal
              clusB-02      configured  enabled  normal
6 entries were displayed.
clusA::> metrocluster node show -partners
              Node (HA Partner) DR Partner (DR Auxiliary)
-----
Cluster:                clusA -
                        clusA-03 (-) - (-)
                        clusA-04 (-) - (-)
Cluster:                clusA clusB
                        clusA-01 (clusA-02) clusB-01 (clusB-02)
                        clusA-02 (clusA-01) clusB-02 (clusB-01)
Cluster:                clusB clusA
                        clusB-01 (clusB-02) clusA-01 (clusA-02)
                        clusB-02 (clusB-01) clusA-02 (clusA-01)
6 entries were displayed.

```

The following example shows the output of the command after after all DR groups in the MetroCluster configuration are configured:

```

clusA::> metrocluster node show
DR
Group Cluster Node      Configuration State  DR
                               Mirroring Mode
-----
1   clusA  clusA-01      configured  enabled  normal
    clusA  clusA-02      configured  enabled  normal
    clusB  clusB-01      configured  enabled  normal
    clusB  clusB-02      configured  enabled  normal
2   clusA  clusA-03      configured  enabled  normal
    clusA  clusA-04      configured  enabled  normal
    clusB  clusB-03      configured  enabled  normal
    clusB  clusB-04      configured  enabled  normal
8 entries were displayed.
clusA::> metrocluster node show -partners
              Node (HA Partner) DR Partner (DR Auxiliary)
-----
Cluster:                clusA clusB

                        clusB-04 (clusB-03) clusA-04 (clusA-03)

```

8 entries were displayed.

## Related Links

- [metrocluster configure](#)

# metrocluster operation show

Display details of the last MetroCluster operation

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **metrocluster operation show** command displays information about the most recent MetroCluster operation run on the local cluster.

This command will display information about all MetroCluster commands except for the commands in the **metrocluster check** directory. This command will not display any information after MetroCluster has been completely unconfigured using the **metrocluster unconfigure** command.

## Examples

The following example shows the output of **metrocluster operation show** after running a [metrocluster configure](#) command was successful:

```
clusA::> metrocluster operation show
      Operation: configure
      State: successful
      Start time: 2/15/2013 18:22:46
      End time: 2/15/2013 18:25:18
      Errors: -
```

## Related Links

- [metrocluster configure](#)

# metrocluster operation history show

Display details of all MetroCluster operations

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **metrocluster operation history show** command displays information about all the MetroCluster operations run on the local cluster.

This command will display information about all MetroCluster commands except for the commands in the **metrocluster check** directory. This command will not display any information after MetroCluster has been completely unconfigured using the **metrocluster unconfigure** command.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-operation-uuid <UUID>] - Identifier for the Operation**

This is the UUID of the operation. If this parameter is specified, only the operation with this UUID is displayed.

**[-cluster <Cluster name>] - Cluster Where the Command Was Run**

This is the name of the cluster where the command was run. If this parameter is specified, only the operations that were run in this cluster are displayed.

**[-node-name <Node name>] - Node Where the Command Was run**

This is the name of the node where the command was run. If this parameter is specified, only the operations that were run on this node are displayed.

**[-operation <MetroCluster Operation Name>] - Name of the Operation**

This is the name of the operation. If this parameter is specified, only the operations with this name are displayed.

**[-start-time <MM/DD/YYYY HH:MM:SS>] - Start Time**

This is the time the operation started execution. If this parameter is specified, only the operations that were started at this time are displayed.

**[-state <MetroCluster Operation state>] - State of the Operation**

This is the state of the operation. If this parameter is specified, only the operations that are in this state are displayed.

**[-end-time <MM/DD/YYYY HH:MM:SS>] - End Time**

This is the time the operation completed. If this parameter is specified, only the operations that completed at this time are displayed.

**[-error-list <text>, ...] - Error List For the Operation**

This is the list of errors that were encountered during an operation's execution. If this parameter is specified, only the operations that have the matching errors are displayed.

**[-job-id <integer>] - Identifier for the Job**

This is the job id for the operation. If this parameter is specified, only the operation that has the matching job id displayed.

**[-additional-info <text>] - Additional Info for Auto Heal**

This is the completion status of the auto heal aggregates and auto heal root aggregates phases when processing switchover with auto heal.

## Examples

The following example shows the output of `metrocluster operation history show` after some MetroCluster operations have been performed:

```
clusA::> metrocluster operation history show
Operation      State      Start time      End time
-----
configure      successful  2/15/2013 18:22:46
                2/15/2013 18:25:18
configure      failed     2/15/2013 18:13:45
                2/15/2013 18:13:45
2 entries were displayed.
```

# metrocluster transition disable

## Disable Transition

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `metrocluster transition disable` command is used to end the transition from a MetroCluster FC to a MetroCluster IP configuration. The command clears the setting for transition mode on the local and partner clusters.

## Examples

The following example shows how to disable the transition mode:

```
clusA::> metrocluster transition disable
clusA::> metrocluster transition show-mode
Transition Mode
```

```
-----  
not-enabled
```

# metrocluster transition enable

## Enable Transition

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `metrocluster transition enable` command is used to start the transition from a MetroCluster FC to a MetroCluster IP configuration. The command sets the transition mode on the local and partner cluster.

## Parameters

**-transition-mode <Mode For FC To Ip Transition> - Transition Mode**

This parameter specifies the setting for the transition-mode.

**[-force {true|false}] - Force enable**

This optional parameter forces the setting for the transition-mode.

## Examples

The following example shows how to enable the non-disruptive transition mode:

```
clusA::> metrocluster transition enable transition-mode non-disruptive  
clusA::> metrocluster transition show-mode  
Transition Mode  
-----  
non-disruptive
```

The following example shows how to enable the disruptive transition mode:

```
clusA::> metrocluster transition enable transition-mode disruptive  
clusA::> metrocluster transition show-mode  
Transition Mode  
-----  
disruptive
```

# metrocluster transition show-mode

Display the transition mode

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `metrocluster transition show-mode` command is used to display the current setting of transition.

## Examples

The following example shows the output of the command when transition is not enabled:

```
clusA::> metrocluster transition show-mode
Transition Mode
-----
not-enabled
```

The following example shows the output of the command when non-disruptive transition is enabled:

```
clusA::> metrocluster transition show-mode
Transition Mode
-----
non-disruptive
```

The following example shows the output of the command when disruptive transition is enabled:

```
clusA::> metrocluster transition show-mode
Transition Mode
-----
disruptive
```

# metrocluster vserver recover-from-partial-switchback

Recover vservers from partial switchback

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `metrocluster vserver recover-from-partial-switchback` command executes the necessary steps needed for a Vserver to be in healthy state after partial completion of the Switchback.

## Parameters

## Examples

```
cluster::> metrocluster vserver recover-from-partial-switchback
```

# metrocluster vserver recover-from-partial-switchover

Recover vservers from partial switchover

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `metrocluster vserver recover-from-partial-switchover` command executes the necessary steps needed for a Vserver to be in healthy state after partial completion of the Switchover.

## Parameters

## Examples

```
cluster::> metrocluster vserver recover-from-partial-switchover
```

# metrocluster vserver resync

Resynchronize Vserver with its partner Vserver

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `metrocluster vserver resync` command resynchronizes the Vserver with its partner Vserver

## Parameters

**-cluster <Cluster name> - Cluster Name**

Name of the cluster where the Vserver belongs

**-vserver <vserver> - Vserver**

Name of the Vserver to be resynchronized

## Examples

```
cluster::> metrocluster vserver resync -cluster clus1 -vserver vs1
```

# metrocluster vserver show

Display MetroCluster Vserver relationships

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **metrocluster vserver show** command displays configuration information for all pairs of Vservers in MetroCluster.

## Parameters

**{ [-fields <fieldname>,...]**

The command output includes the specified field or fields

**| [-creation-time ]**

Shows the last configuration modification time on the Vserver

**| [-instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-cluster <Cluster name>] - Cluster Name**

Name of the cluster where the Vserver belongs

**[-vserver <vserver>] - Vserver**

Name of the Vserver

**[-partner-vserver <vserver>] - Partner Vserver**

Name of the partner Vserver

**[-configuration-state {healthy|unhealthy|degraded|pending-setup|syncing|replication-paused|pending-switchback}] - Configuration State**

Configuration states include:

- **healthy**
- **unhealthy**
- **degraded** indicates that Vservers are not in sync
- **syncing** indicates that the Vserver configuration is being synchronized
- **replication-paused** indicates that the configuration replication was manually paused
- **pending-setup** indicates that partner Vserver creation is pending

**[-corrective-action <text>] - Corrective Action**

Corrective action which can be followed to successfully create the partner Vserver

**[-creation-time-of-last-applied-change <MM/DD/YYYY HH:MM:SS>] - Creation Time on the Source**

Last configuration modification time on the Vserver

**[-failed-row <smbd-row-op>] - Failed Row**

Failed replication row

**[-failed-object <text>] - Failed Object**

Displays the failed object name

**[-failed-reason <text>] - Failed Replication Reason**

Failed replication reason

**[-out-of-sync <>true>] - Is Out of Sync**

Indicates that the Vserver configuration replication is not in sync

**[-config-resume-time <MM/DD/YYYY HH:MM:SS>] - Configuration Resume Time**

Displays the resume time of the Vserver configuration replication

**[-irrecoverable-apply-failed-reason <text>] - Reason for Failure**

Reason for the replication failure

## Examples

The following example shows the output of the command when partner Vservers are created

```
clusA::> metrocluster vserver show
Cluster: clusA
```

Vserver	Partner Vserver	Configuration State
clusA	clusB	healthy

```

vs1                vs1-mc                healthy
Cluster: clusB
Vserver            Partner                Configuration
-----            Vserver            State
-----
clusB              clusA                healthy
3 entries were displayed.

```

The following example shows the output of the command when the partner Vserver creation is pending

```

clusA::> metrocluster vserver show
Cluster: clusA
Vserver            Partner                Configuration
-----            Vserver            State
-----
clusA              clusB                healthy
vs1                -                    pending-setup
Corrective Action: Create Ipspace ips1 on the partner cluster.
2 entries were displayed.

```

## network ping

### Ping

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **network ping** command displays whether a remote address is reachable and responsive, the (if specified) number of transmitted and received packets, and their round-trip time. The command requires a source node or logical interface from where the ping will be run, and a destination IP address. You can specify the source node by name, or a logical interface and its Vserver.

## Parameters

{ **-node <nodename>** - **Node**

Use this parameter to send the ping from the node you specify.

| **-lif <lif-name>** - **Logical Interface** }

Use this parameter to send the ping from the logical interface you specify.

**-vserver <vserver> - Vserver**

Use this parameter to send the ping from the Vserver where the intended logical interface resides. The default value is the system Vserver for cluster administrators.

**[-use-source-port {true|false}] - (DEPRECATED)-Use Source Port of Logical Interface**

This parameter is only applicable when the **-lif** parameter is specified. When set to true, the ping packet will be sent out via the port which is currently hosting the IP address of the logical interface. Otherwise, the ping packet will be sent out via a port based on the routing table.

The **use-source-port** parameter is deprecated and may be removed in a future release of Data ONTAP.

**-destination <Remote InetAddress> - Destination**

Use this parameter to specify the remote internet address destination of the ping.

**[-s, -show-detail <true>] - Show Detail Output**

Use this parameter to display detailed output about the ping.

**[-R, -record-route <true>] - Record Route**

Use this parameter to display the route followed by the ping. You should set this option to **false** for pinging to succeed.

**[-v, -verbose <true>] - Show All ICMP Packets**

Use this parameter to display all ICMP packets.

**[-packet-size <integer>] - Packet Size**

Use this parameter to specify the number of data bytes to be sent in the ping packet. The default is 56 bytes, which is 64 ICMP data bytes total after 8 bytes of ICMP header data is added.

**[-count <integer>] - Count**

Use this parameter to specify the maximum number of ECHO\_REQUESTS to be sent to the destination. The default is 20 requests. In the absence of the 'show-detail' option, ping reports that the destination is alive after receiving the first ECHO\_REPLY response, independent of this value.

**[-wait <integer>] - Packet Send Wait Time (secs)**

Use this parameter to specify the number of seconds to wait between sending packets. The default is one second.

**[-flood <true>] - Flood Ping**

Use this parameter to execute the command in flood mode. In flood mode, the command issues pings as fast as they are received, unless you specify a wait time.

**[-D, -disallow-fragmentation <true>] - Disallow Packet Fragmentation**

Use this parameter to prevent transport mechanisms from fragmenting ping packets in transit. Preventing fragmentation assures consistent packet size, making it easier to see transport bottlenecks.

**[-wait-response <integer>] - Packet Response Wait Time (ms)**

Use this parameter to specify the number of milliseconds to wait for each response packet. The default is 10000 milliseconds (10 seconds).

## Examples

This example shows a ping from node xena to the destination server 10.98.16.164 with the server responding that it is up and running.

```
cluster1::> network ping -node xena -destination 10.98.16.164
(network ping)
10.98.16.164 is alive
```

# network ping6

Ping an IPv6 address

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **network ping6** command uses the ICMPv6 protocol's mandatory ICMP6\_ECHO\_REQUEST datagram to elicit an ICMP6\_ECHO\_REPLY from a host or gateway. ICMP6\_ECHO\_REQUEST datagrams ("pings") have an IPv6 header, and ICMPv6 header formatted as documented in RFC2463.

## Parameters

**{ -node <nodename> - Node Name**

Use this parameter to originate ping6 from the specified node.

**| -lif <lif-name> - Logical Interface }**

Use this parameter to originate ping6 from the specified logical interface.

**-vserver <vserver name> - Vserver Name**

Use this parameter to originate ping6 from the specified Vserver. The default value is the system Vserver for cluster administrators.

**-destination <Remote InetAddress> - Destination**

Use this parameter to specify the IPv6 address of the destination node.

**[-b, -buffer-size <integer>] - Socket Buffer Size**

Use this parameter to set the socket buffer size.

**[-c, -count <integer>] - Max Requests to Send/Receive**

Use this parameter to specify the maximum number of requests and replies. The default value is 20.

**[-H, -reverse-lookup <true>] - Reverse-lookup of IPv6 addresses**

Use this parameter to specify reverse-lookup of IPv6 addresses. Unless this parameter is specified, ping6 command does not attempt reverse lookup.

**[-i, -interval <integer>] - Wait between Packets (secs)**

Use this parameter to specify the delay time between packets in seconds. The default value is 1 second. This parameter is incompatible with the flood parameter.

**[-l, -preload <integer>] - Send Packets as Fast as Possible**

Use this parameter if preload is required. If specified, ping6 sends that many packets as fast as possible before falling into its normal mode of behaviour.

**[-use-source-port {true|false}] - Use Source Port of Logical Interface**

This parameter is only applicable when the -lif parameter is specified. When set to true, the ping packet will be sent out via the port which is currently hosting the IP address of the logical interface. Otherwise, the ping packet will be sent out via a port based on the routing table.

**[-p, -pattern <text>] - Up to 16 'pad' Specified for Out Packet**

Use this parameter to fill the -16 'pad' bytes in the sent packet. This is useful for diagnosing data dependent problems in a network. For example, -pattern ff causes the sent packet to be filled with all ones.

**[-packet-size <integer>] - Packet Size**

Use this parameter to specify the number of data bytes to be sent. The default is 56, which translates to 64 ICMP data bytes when combined with the 8 bytes of ICMP header data.

**[-v, -verbose <true>] - Show All ICMP Packets**

Use this parameter to get verbose output. Verbose output displays both source address and destination addresses. Received ICMP packets other than ECHO\_RESPONSE are listed. This parameter can be used only in conjunction with the show-detail parameter.

**[-s, -show-detail <true>] - Show Detail Output**

Use this parameter to display detailed output about the ping.

**[-f, -flood <true>] - Flood Ping**

Use this parameter to output packets as fast as they come back or one hundred times per second, whichever is more. For every ECHO\_REQUEST sent a period "." is printed, while for every ECHO\_REPLY received a backspace is printed. This provides a rapid display of how many packets are being dropped. This can be very hard on a network and should be used with caution.

**[-D, -disable-fragmentation <true>] - Disable Fragmentation.**

Use this parameter to disallow fragmentation of the outgoing packets, if they do not fit in the Maximum Transmission Unit.

## Examples

This example shows a ping6 from node 'node1' to the destination server ipv6.google.com with the server responding that it is up and running.

```
cluster1::> network ping6 -node node1 -destination ipv6.google.com
ipv6.google.com is alive.
```

## network test-path

Test path performance between two nodes

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

The **network test-path** command runs a performance test between two nodes. The command requires a source node, destination node, destination cluster, and application, or session type. All tests are run using intracluster or intercluster LIFs, depending on whether the test is between two nodes in the same cluster, or between nodes in peered clusters.

The test itself is different from most bandwidth test tools. It creates a "session" consisting of TCP connections between all possible paths between the nodes being tested. This is how internal Data ONTAP applications communicate between nodes. This means the test is using multiple paths, and thus the bandwidth reported might exceed the capacity of a single 10 Gb path.

### Parameters

**-source-node {<nodename>|local} - Node Initiating Session**

Use this parameter to specify the node that initiates the test. Source-node parameter must be a member of the cluster in which the command is run.

**-destination-cluster <Cluster name> - Cluster Containing Passive Node**

Use this parameter to specify the destination cluster; the local cluster, or a peered cluster.

**-destination-node <text> - Remote Node in Destination Cluster**

Use this parameter to specify the destination node in the destination cluster

**-session-type {AsyncMirrorLocal|AsyncMirrorRemote|RemoteDataTransfer} - Type of Session to Test**

The session type parameter is used to mimic the application settings used. A session consists of multiple TCP connections.

- AsyncMirrorLocal: settings used by SnapMirror between nodes in the same cluster
- AsyncMirrorRemote: settings used by SnapMirror between nodes in different clusters

- RemoteDataTransfer: settings used by Data ONTAP for remote data access between nodes in the same cluster

The default session-type is AsyncMirrorRemote.

### **[-connection-detail {true|false}] - Display Test Results per Network Path**

Boolean argument to specify if the network test-path run should be executed for specific network paths. This defaults to false.

## Examples

The following example runs a test between two nodes in the same cluster:

```
cluster1::*> network test-path -source-node node1 -destination-cluster cluster1
-destination-node node2
Test Duration: 10.65 secs
  Send Throughput: 1092.65 MB/sec
  Receive Throughput: 1092.65 MB/sec
    MB Sent: 11633.69
    MB Received: 11633.69
    Avg Latency: 64.40 ms
    Min Latency: 2.41 ms
    Max Latency: 2099.17 ms
```

# network traceroute

## Traceroute

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **network traceroute** command performs a network probe from a node to a specified IP address. The command requires a source node or logical interface and a destination IP address. You can specify the source node by name, or specify a logical interface and its Vserver. The traceroute is performed between the source and destination.

## Parameters

### **{ -node <nodename> - Node**

Use this parameter to originate the traceroute from the node you specify.

### **|-lif <lif-name> - Logical Interface }**

Use this parameter to originate the traceroute from the specified network interface.

**-vserver <vserver> - LIF Owner**

Use this parameter to originate the traceroute from the Vserver where the intended logical interface resides. The default value is the system Vserver for cluster administrators.

**-destination <Remote InetAddress> - Destination**

Use this parameter to specify the remote internet address destination of the traceroute.

**[-m, -maxttl <integer>] - Maximum Number of Hops**

Use this parameter to specify the maximum number of hops (time-to-live) setting used by outgoing probe packets. The default is 30 hops.

**[-n, -numeric <true>] - Print Hop Numerically**

Use this parameter to print the hop addresses only numerically rather than symbolically and numerically.

**[-port <integer>] - Base UDP Port Number**

Use this parameter to specify the base UDP port number used in probes. The default is port 33434.

**[-packet-size <integer>] - Packet Size**

Use this parameter to specify the size of probe packets, in bytes.

**[-q, -nqueries <integer>] - Number of Queries**

Use this parameter to specify the number of probes per hop. The default is 3 probes.

**[-v, -verbose <true>] - Verbose Output**

Use this parameter to display all received ICMP packets, rather than just TIME\_EXCEEDED and UNREACHABLE packets.

**[-w, -waittime <integer>] - Wait Between Packets (secs)**

Use this parameter to specify the time (in seconds) to wait for the response to a probe. The default is 5 seconds.

## Examples

This example shows a traceroute from node node1 to a destination address of 10.98.16.164, showing a maximum of five hops.

```
cluster1::> traceroute -node node1 -destination 10.98.16.164 -maxttl 5
 1  10.68.208.1 <10.68.208.1> 0.307 ms 293 ms 305 ms
 2  152.164.13.205 <152.164.13.205> 3.754 ms 3.722 ms 3.981 ms
 3  68.137.122.222 <68.137.122.222> 25.603 ms 24.947 ms 24,565 ms
 4  * * *
 5  * * *
```

```
traceroute to 10.98.16.164, 5 hops max, 52 byte packets
```

# network traceroute6

## traceroute6

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **network traceroute6** command performs a network probe from a node to a specified IPv6 address. The command requires a source node or logical interface, Vserver from where traceroute6 will originate and a destination IPv6 address. traceroute6 is performed between the source and destination.

## Parameters

### { -node <nodename> - Node

Use this parameter to originate traceroute6 from the node you specify. This parameter is available only to cluster administrators.

### | -lif <lif-name> - Logical Interface }

Use this parameter to originate traceroute6 from the logical interface you specify.

### -vserver <vserver name> - LIF Owner

Use this parameter to originate traceroute6 from the Vserver you specify. The default value is the system Vserver for cluster administrators.

### [-d, -debug-mode <>true>] - Debug Mode

Use this parameter to enable socket level debugging. The default value is false.

### { [-I, -icmp6 <>true>] - ICMP6 ECHO instead of UDP

Use this parameter to specify the use of ICMP6 ECHO instead of UDP datagrams for the probes. The default value is false.

### [-U, -udp <>true>] - UDP }

Use this parameter to specify the use of UDP datagrams for the probes. The default value is true.

### [-n, -numeric <>true>] - Print Hops Numerically

Use this parameter to print the hop addresses only numerically rather than symbolically and numerically. The default value is false.

### [-v, -verbose <>true>] - Verbose Output

Use this parameter to display all received ICMP packets, rather than just TIME\_EXCEEDED and UNREACHABLE packets. The default value is false.

**[-f, -first-hop <integer>] - Number of Hops to Skip in Trace**

Use this parameter to specify the number of hops to skip in trace. The default value is 1.

**[-g, -gateway <Remote InetAddress>] - Intermediate Gateway**

Use this parameter to specify the intermediate gateway.

**[-m, -hop-limit <integer>] - Maximum Number of Hops**

Use this parameter to specify the maximum hoplimit, upto 255. The default value is 64 hops.

**[-p, -port <integer>] - Base UDP Port Number**

Use this parameter to specify the base UDP port number used in probes. The default value is port 33434.

**[-q, -nqueries <integer>] - Number of Queries**

Use this parameter to specify the number of probes per hop. The default value is 3 probes.

**[-w, -wait-time <integer>] - Wait Between Packets (secs)**

Use this parameter to specify the delay time between probes in seconds. The default value is 5 seconds.

**-destination <Remote InetAddress> - Destination**

Use this parameter to specify the remote IPv6 address destination of traceroute6.

**[-packet-size <integer>] - Packet Size**

Use this parameter to specify the size of probe packets, in bytes. The default value is 16 bytes for ICMP6 ECHO and 12 bytes for UDP datagrams.

## Examples

The following example shows traceroute6 from node node1 to the destination fd20:8b1e:b255:4071:d255:1fcd:a8cd:b9e8.

```
cluster1::> network traceroute6 -node node1 -server vs1
               -destination 3ffe:b00:c18:1::10
traceroute6 to 3ffe:b00:c18:1::10 (3ffe:b00:c18:1::10)
               from 2001:0db8:0000:f101::2,
               64 hops max, 12 byte packets
 1 2001:0db8:0000:f101::1 4.249 ms  2.021 ms  0.864 ms
 2 3ffe:2000:0:400::1 0.831 ms  0.579 ms
 3 3ffe:2000:0:1::132 227.693 ms  227.596 ms  227.439 ms
 4 3ffe:c00:8023:2b::2 229.028 ms  228.267 ms  231.891 ms
 5 3ffe:2e00:e:c::3 227.929 ms  228.696 ms  228.558 ms
 6 3ffe:b00:c18:1::10 227.702 ms  227.806 ms  227.439 ms
```

# network arp create

Create static ARP entry

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **network arp create** command creates a static ARP entry for a given Vserver. Statically created ARP entries will be stored permanently in the Vserver context and will be used by the network stack.

## Parameters

**-vserver <vserver name> - Vserver Name**

Use this parameter to specify the name of the Vserver on which the ARP entry is created.

**-remotehost <IP Address> - Remote IP Address**

Use this parameter to specify the IP address to be added as an ARP entry.

**-mac <MAC Address> - MAC Address**

Use this parameter to specify the MAC address (Ethernet address) for the host specified with **-remotehost**. Specify the MAC address as six hex bytes separated by colons.

## Examples

The following example creates a static ARP entry on Vserver vs1 for the remote host with the IP address 10.63.0.2 having MAC address 40:55:39:25:27:c1

```
cluster1::> network arp create -vserver vs1 -remotehost 10.63.0.2 -mac  
40:55:39:25:27:c1
```

# network arp delete

Delete static ARP entry

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **network arp delete** command deletes static ARP entries from the Vserver and from the network stack.

## Parameters

**-vserver <vserver name> - Vserver Name**

Use this parameter to specify the name of the Vserver from which the ARP entry is deleted.

**-remotehost <IP Address> - Remote IP Address**

Use this parameter to specify the IP address of the ARP entry being deleted.

## Examples

The following example deletes the ARP entry for IP address 10.63.0.2 from the Vserver vs1.

```
cluster1::> network arp delete -vserver vs1 -remotehost 10.63.0.2
```

# network arp show

Display static ARP entries

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **network arp show** command displays static ARP entries present in a given Vserver. This command will not display dynamically learnt ARP entries in the network stack. Use the [network arp active-entry show](#) command to display dynamically learned ARP entries in the network stack.

## Parameters

**{ [-fields <fieldname>,...]**

Use this parameter to display only certain fields of the ARP table.

**| [-instance ] }**

Use this parameter to display all the fields of the ARP table.

**[-vserver <vserver name>] - Vserver Name**

Use this parameter to display ARP entries that are specific to a given Vserver.

**[-remotehost <IP Address>] - Remote IP Address**

Use this parameter to display ARP entries for the specified IP address

**[-mac <MAC Address>] - MAC Address**

Use this parameter to display ARP entry for the specified MAC address

**[-ipSPACE <IPspace>] - IPspace**

Use this parameter to specify the IPspace associated with the Vserver

## Examples

The following example displays static ARP entries from the Vserver vs1.

```
cluster1::> network arp show -vserver vs1
Vserver      Remote Host      MAC Address
-----
vs1
             10.238.0.2      40:55:39:25:27:c1
```

## Related Links

- [network arp active-entry show](#)

# network arp active-entry delete

Delete active ARP entry from a System or Admin Vserver

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **network arp active-entry delete** command deletes dynamically learned ARP entries from the network stack of a node. To delete statically configured ARP entries use the [network arp delete](#) command.

## Parameters

**-node {<nodename>|local} - Node**

Use this parameter to specify the name of the node in which the ARP entry is deleted.

**-vserver <vserver> - System or Admin Vserver Name**

Use this parameter to specify the name of the Vserver in which the ARP entry is deleted. Only Vservers with a type of Admin or System have dynamically learned ARP entries.

**-subnet-group <IP Address/Mask> - Subnet Group Name**

Use this parameter to specify the name of the routing group in which the ARP entry is deleted.

**-remotehost <text> - Remote IP Address**

Use this parameter to specify the IP address to be deleted from the active ARP entries.

**-port <text> - Port**

Use this parameter to specify the name of the Port to be deleted from the active ARP entries.

## Examples

The following example deletes the active ARP entry with an IP address of 10.224.64.1, subnet group of 0.0.0.0/0, port e0c on node node2 in the Admin Vserver cluster1:

```
cluster1::*> network arp active-entry delete -node cluster1-01 -vserver cluster1
-subnet-group 0.0.0.0/0 -remotehost 10.224.64.1 -port e0c
```

## Related Links

- [network arp delete](#)

# network arp active-entry show

Display active ARP entries organized by Vserver

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `network arp active-entry show` command displays ARP entries present in the network stack of the node. The entries includes both dynamically learned ARP entries and user configured static ARP entries.

## Parameters

**{ [-fields <fieldname>,...]**

Use this parameter to display only certain fields of the active ARP table.

**| [-instance ] }**

Use this parameter to display all the fields of the active ARP table.

**[-node {<nodename>|local}] - Node**

Use this parameter to display active ARP entries that are specific to a given node.

**[-vserver <vserver>] - System or Admin Vserver Name**

Use this parameter to display active ARP entries that are specific to a given System or Admin Vserver. Data and Node Vservers will not have any active-arp entries.

**[-subnet-group <IP Address/Mask>] - Subnet Group Name**

Use this parameter to display active ARP entries that are specific to a given subnet group.

**[-remotehost <text>] - Remote IP Address**

Use this parameter to display active ARP entries for the specified IP address.

**[-port <text>] - Port**

Use this parameter to display active ARP entries for the specified Port name.

**[-mac <text>] - MAC Address**

Use this parameter to display the active ARP entry for the specified MAC address.

**[-ipSPACE <IPspace>] - IPspace**

Use this parameter to specify the IPspace associated with the System or Admin Vserver.

## Examples

The following example displays active ARP entries for the Admin Vserver cluster1:

```
cluster1::*> network arp active-entry show -vserver cluster1
```

```
Node: node-01
```

```
Vserver: cluster1
```

```
Subnet Group: 169.254.0.0/16
```

Remote IP Address	MAC Address	Port
169.254.106.95	0:55:39:27:d1:c1	lo

# network bgp config create

Create BGP configuration

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `network bgp config create` command is used to create the border gateway protocol (BGP) configuration for a node. It can be used to override the BGP parameters defined in the global BGP defaults.

## Parameters

**-node {<nodename>|local} - Node**

This parameter specifies the node on which configuration details will be created.

**-asn <integer> - Autonomous System Number**

This parameter specifies the autonomous system number (ASN). The ASN attribute is a positive integer of the range from 1 to 4,294,967,295. It should typically be chosen from RFC6996

"Autonomous System (AS) Reservation for Private Use" or the AS number assigned to the operator's organization.

**-hold-time <integer> - Hold Time**

This parameter specifies the hold time in seconds. The default value is 180.

**-router-id <IP Address> - Router ID**

This parameter specifies the local router ID. The router-id value takes the form of an IPv4 address. The default router-id will be initialized using a local IPv4 address in admin vserver.

## Examples

```
cluster1::> network bgp config create -node node1 -asn 10 -hold-time 180 -router-id 10.0.1.112
```

# network bgp config delete

Delete BGP configuration

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **network bgp config delete** command deletes a node's border gateway protocol (BGP) configuration. A BGP configuration cannot be deleted if there are BGP peer groups configured on the associated node.

## Parameters

**-node {<nodename>|local} - Node**

This parameter specifies the node for which the BGP configuration will be deleted.

## Examples

```
cluster1::> network bgp config delete -node node1
```

# network bgp config modify

Modify BGP configuration

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **network bgp config modify** command is used to modify a node's border gateway protocol (BGP) configuration.

## Parameters

**-node {<nodename>|local} - Node**

This parameter specifies the node on which BGP configuration will be modified.

**[-asn <integer>] - Autonomous System Number**

This parameter specifies the autonomous system number (ASN). The ASN attribute is a positive integer of the range from 1 to 4,294,967,295. It should typically be chosen from RFC6996 "Autonomous System (AS) Reservation for Private Use" or the AS number assigned to the operator's organization.

**[-hold-time <integer>] - Hold Time**

This parameter specifies the hold time in seconds.

**[-router-id <IP Address>] - Router ID**

This parameter specifies the local router ID. The router-id value takes the form of an IPv4 address.

## Examples

```
cluster1::> network bgp config modify -node node1 -router-id 1.1.1.1 -asn 20
```

## network bgp config show

Display BGP configuration

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **network bgp config show** command displays the border gateway protocol (BGP) configuration for each node.

## Parameters

**{ [-fields <fieldname>, ...]**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[`-instance`] }**

If you specify the `-instance` parameter, the command displays detailed information about all fields.

**[`-node` {<nodename>|local}] - Node**

This parameter selects the BGP configurations that match the specified node.

**[`-asn` <integer>] - Autonomous System Number**

This parameter selects the BGP configurations that match the specified autonomous system number.

**[`-hold-time` <integer>] - Hold Time**

This parameter selects BGP configurations that match the specified hold time.

**[`-router-id` <IP Address>] - Router ID**

This parameter selects the BGP configurations that match the specified router ID.

## Examples

```
cluster1::> network bgp config show
  Autonomous
  System    Hold Time
  Node      Number    (seconds) Router ID
-----
node1      10        180      10.0.1.112
```

# network bgp defaults modify

Modify BGP defaults

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `network bgp defaults modify` command modifies the global defaults for border gateway protocol (BGP) configurations.

## Parameters

**[`-asn` <integer>] - Autonomous System Number**

This parameter specifies the autonomous system number (ASN). The ASN attribute is a positive integer. It should typically be chosen from RFC6996 "Autonomous System (AS) Reservation for Private Use", or the AS number assigned to the operator's organization. The default ASN is 65501.

## **[-hold-time <integer>] - Hold Time**

This parameter specifies the hold time in seconds. The default value is 180.

## Examples

```
cluster1::> network bgp defaults modify -asn 20
```

# network bgp defaults show

Display BGP defaults

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **network bgp defaults show** command displays the global defaults for border gateway protocol (BGP) configurations.

## Examples

```
cluster1::> network bgp defaults show
Autonomous
System Number  Hold Time
(Seconds)
-----
10             180
```

# network bgp peer-group create

Create a new BGP peer group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **network bgp peer-group create** command is used to create a border gateway protocol (BGP) peer group. A BGP peer group will advertise VIP routes for the list of vservers in the peer group's **vserver-list** using the BGP LIF of the peer group. A BGP peer group will advertise VIP routes to a peer router using the border gateway protocol. The address of the peer router is identified by the **peer-address** value.

## Parameters

### **-ip-space <IPspace> - IPspace Name**

This parameter specifies the IPspace of the peer group being created.

### **-peer-group <text> - Peer Group Name**

This parameter specifies the name of the peer group being created.

### **-bgp-lif <lif-name> - BGP LIF**

This parameter specifies the BGP interface (BGP LIF) of the peer group being created.

### **-peer-address <IP Address> - Peer Router Address**

This parameter specifies the IP address of the peer router for the peer group being created.

### **[-peer-asn <integer>] - Peer Router Autonomous number**

This parameter specifies the peer router autonomous system number (ASN) in the peer group being created. The default value is the value of the local node's ASN.

### **-route-preference <integer> - Route Preference**

This parameter specifies the preference field in BGP update messages for VIP routes. If a router receives multiple VIP route announcements for the same VIP LIF from different BGP LIFs, it will install the one that has the highest preference value. The default route preference value is 100.

### **[-asn-prepend-type <ASN Prepend type>] - ASN prepend type**

This parameter specifies the ASN that will be prepended in the BGP attributes. The possible values are **local-asn** and **peer-asn**. The default behaviour is not to prepend any ASN.

### **[-asn-prepend-count <integer>] - ASN prepend count**

This parameter specifies the number of times ASN, as specified in **asn-prepend-type** will be prepended in the BGP path attributes. The default behaviour is not to prepend any ASN.

### **[-community <BGP community>,...] - BGP Community**

This parameter specifies the communities that will be included in the BGP path attributes. The default behaviour is not to include any community in BGP path attributes.

### **[-med <integer>] - Multi Exit Discriminator**

This parameter specifies the Multi Exit Discriminator (MED) attribute of BGP update messages, which can be used by routers for best path selection, in cases where more than one peer advertises the same route with similar attributes.

### **[-use-peer-as-next-hop {true|false}] - Use Peer Address As Next Hop**

This parameter specifies whether the peer group uses the peer address as a next hop route. When the value is true, the peer address is used as the next hop router for packets sent from VIP LIFs via the port on which **bgp-lif** is configured. Internally, a default route with a gateway configured as the **peer-address** is added automatically on the node for all the Vservers in this peer group's IPspace. The route will be added for a Vserver only if it has a VIP LIF hosted on the current node of **bgp-lif**. Note that these automatically installed default routes are for VIP traffic; however, they

can be used for non-VIP traffic as well if a Vserver hosts both VIP and non-VIP LIFs in the same subnet as **bgp-lif** . This route will have metric of 20 and will be used to forward traffic through the current port of **bgp-lif** . The default value of this parameter is false.

## Examples

```
cluster1::> network bgp peer-group create -peer-group group1 -ip-space Default -bgp-lif
bgp_lif -peer-address 10.0.1.112
```

# network bgp peer-group delete

Delete a BGP peer group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **network bgp peer-group delete** command is used to delete border gateway protocol (BGP) peer group configuration.

## Parameters

**-ip-space <IPspace> - IPspace Name**

This parameter specifies the IPspace of the BGP peer group being deleted.

**-peer-group <text> - Peer Group Name**

This parameter specifies the name of the BGP peer group being deleted.

## Examples

```
cluster1::> network bgp peer-group delete -ip-space Default -peer-group group1
```

# network bgp peer-group modify

Modify a BGP peer group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **network bgp peer-group modify** command is used to modify a border gateway protocol (BGP) peer group configuration.

## Parameters

### **-ipSPACE <IPspace> - IPspace Name**

This parameter specifies the IPspace of the peer group being modified.

### **-peer-group <text> - Peer Group Name**

This parameter specifies the name of the peer group being modified.

### **[-peer-address <IP Address>] - Peer Router Address**

This parameter specifies an updated value for the IP address of the peer router.

### **[-use-peer-as-next-hop {true|false}] - Use Peer Address As Next Hop**

This parameter specifies whether the peer group uses the peer address as a next hop route. When the value is true, the peer address is used as the next hop router for packets sent from VIP LIFs via the port on which **bgp-lif** is configured. Internally, a default route with a gateway configured as the **peer-address** is added automatically on the node for all the Vservers in this peer group's IPspace. The route will be added for a Vserver only if it has a VIP LIF hosted on the current node of **bgp-lif**. Note that these automatically installed default routes are for VIP traffic; however, they can be used for non-VIP traffic as well if a Vserver hosts both VIP and non-VIP LIFs in the same subnet as **bgp-lif**. This route will have metric of 20 and will be used to forward traffic through the current port of **bgp-lif**. The default value of this parameter is false.

## Examples

```
cluster1::> network bgp peer-group modify -ipSPACE Default -peer-group peer1 -peer  
-address 10.10.10.10
```

## network bgp peer-group rename

Rename a BGP peer group

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **network bgp peer-group rename** command is used to assign a new name to a BGP peer group.

## Parameters

### **-ipSPACE <IPspace> - IPspace Name**

This parameter specifies the IPspace of the peer group being renamed.

### **-peer-group <text> - Peer Group Name**

The name of the peer group to be updated.

**-new-name <text> - New Name**

The new name for the peer group.

## Examples

```
cluster1::> network bgp peer-group rename -peer-group old_name -new-name new_name
```

# network bgp peer-group show

Display BGP peer groups information

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **network bgp peer-group show** command displays the BGP peer groups configuration.

## Parameters

{ [-fields <fieldname>, ...]

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance ]}

If you specify the **-instance** parameter, the command displays detailed information about all fields.

[-ip-space <IPspace>] - IPspace Name

This parameter selects peer groups that match the specified IPspace.

[-peer-group <text>] - Peer Group Name

This parameter selects peer groups that match the specified name.

[-bgp-lif <lif-name>] - BGP LIF

This parameter selects peer groups that match the specified BGP Interface.

[-peer-address <IP Address>] - Peer Router Address

This parameter selects peer groups that match the specified peer router address.

[-peer-asn <integer>] - Peer Router Autonomous number

This parameter selects peer groups that match the specified autonomous system number.

[-state <BGP Session State>] - Peer Group State

This parameter selects peer groups that match the specified BGP session state.

**[-bgp-node <nodename>] - BGP LIF Node**

This parameter selects peer groups that match the specified **bgp-node** value. This value is calculated based on the current node of the corresponding BGP LIF.

**[-bgp-port <netport>] - BGP LIF Port**

This parameter selects peer groups that match the specified **bgp-port** value. This value is calculated based on the current port of the associated BGP LIF.

**[-route-preference <integer>] - Route Preference**

This parameter selects peer groups that match the specified route preference value.

**[-asn-prepend-type <ASN Prepend type>] - ASN prepend type**

This parameter selects peer groups that match the specified **asn-prepend-type** value. The possible values are **local-asn** and **peer-asn**.

**[-asn-prepend-count <integer>] - ASN prepend count**

This parameter selects peer groups that match the specified **asn-prepend-count** value.

**[-community <BGP community>,...] - BGP Community**

This parameter selects peer groups that match the specified **community** value.

**[-med <integer>] - Multi Exit Discriminator**

This parameter selects peer groups that match the specified med value.

**[-use-peer-as-next-hop {true|false}] - Use Peer Address As Next Hop**

This parameter selects peer groups that match the specified use-peer-as-next-hop value.

## Examples

```
cluster1::> network bgp peer-group show
IPspace: Default
Peer      Local BGP Peer router      Autonomous
Group     Interface Address/subnet  state      Number    Node    Port
-----
gp1       bgp_lif1  10.0.5.37      up         10       node1   e1a
gp2       bgp_lif2  10.0.6.38      up         12       node1   e2a
```

# network bgp vserver-status show

Display Vserver BGP status

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `network bgp vserver-status show` command displays the per-node border gateway protocol (BGP) status for each vserver. The BGP status for a particular vserver is "up" when at least one BGP peer group supporting that vserver is able to communicate with its peer router.

## Parameters

`{ [-fields <fieldname>, ... ] }`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

`[ -instance ] }`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[ -node {<nodename>|local} ] - Node`

This parameter selects the BGP status that match the specified node.

`[ -vserver <vserver name> ] - Vserver`

This parameter selects the BGP status for specified vserver.

`[ -ipv4-status {unknown|unconfigured|up|down} ] - IPv4 status`

This parameter selects the BGP status that matches the specified status for IPv4 address family.

`[ -ipv6-status {unknown|unconfigured|up|down} ] - IPv6 status`

This parameter selects the BGP status that matches the specified status for IPv6 address family.

## Examples

```
cluster1::> network bgp vserver-status show
Node          vserver  IPv4 status IPv6 status
-----
node1         vs1      up          up
```

## network cloud routing-table create

Create a new external routing table

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `network cloud routing-table create` command creates a new external routing table.

## Parameters

**-route-table-id <text> - Route Table ID**

This parameter is used to provide the name of the external routing table to be created.

## Examples

The following example creates an external routing table "eni-123456":

```
cluster1::> network cloud routing-table create -route-table-id eni-123456
```

# network cloud routing-table delete

Delete an existing external routing table

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **network cloud routing-table delete** deletes an existing external routing table.

## Parameters

**-route-table-id <text> - Route Table ID**

This parameter is used to provide the name of an existing external routing table to be deleted.

## Examples

The following example deletes the external routing table "eni-123456":

```
cluster1::> network cloud routing-table delete -route-table-id eni-123456
```

# network cloud routing-table show

Show existing external routing tables

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **network cloud routing-table show** command retrieves the configured routing tables on mediator and displays them.

## Parameters

{[-fields <fieldname>,...]}

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance ]}

If you specify the **-instance** parameter, the command displays detailed information about all fields.

[-route-table-id <text>] - Route Table ID

This parameter is the name of the external routing table to be shown.

## Examples

The following example shows external routing tables, for this cluster, that are configured on the mediator

```
cluster1::> network cloud routing-table show
Route Table ID
-----
rtb-16924571
rtb-9c9245fb
rtb-a36ca1c4
3 entries were displayed.
```

# network connections active show-clients

Show a count of the active connections by client

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **network connections active show-clients** command displays information about client connections, including the client's IP address and the number of client connections.

The results of this command set are refreshed independently every 30 seconds and might not reflect the immediate state of the system.

## Parameters

{[-fields <fieldname>,...]}

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the

specified field or fields. You can use '-fields ?' to display the fields to specify.

### [**-instance** ] }

If you specify the **-instance** parameter, the command displays detailed information about all fields.

### [**-node** {<nodename>|local}] - Node

Use this parameter to display information only about the connections on the node you specify.

### [**-vserver** <vserver>] - Vserver

This parameter is used by the system to break down the output per vservers.

### [**-remote-address** <Remote IP>] - Remote IP Address

Use this parameter to display information only about the connections that use the remote IP address you specify.

### [**-count** <integer>] - Client Count

Use this parameter to only clients with the number of active client connections you specify.

## Examples

The following example displays information about active client connections:

```
cluster1::> network connections active show-clients
Node      Vserver Name      Client IP Address      Count
-----
node0     vs1                192.0.2.253           1
         vs2                192.0.2.252           2
         vs3                192.0.2.251           5
node1     vs1                192.0.2.250           1
         vs2                192.0.2.252           3
         vs2                customer.example.com   4
```

## network connections active show-lifs

Show a count of the active connections by logical interface

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **network connections active show-lifs** command displays the number of active connections on each logical interface, organized by node and Vserver.

The results of this command set are refreshed independently every 30 seconds and

might not reflect the immediate state of the system.

## Parameters

### { [-fields <fieldname>, ... ] }

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

### [ [-instance ] ] }

If you specify the **-instance** parameter, the command displays detailed information about all fields.

### [-node {<nodename>|local}] - Node

Use this parameter to display information only about the connections on the node you specify.

### [-vserver <vserver>] - Vserver

Use this parameter to display information only about the connections that are using the node or Vserver you specify.

### [-lif-name <lif-name>] - Logical Interface Name

Use this parameter to display information only about the connections that are using the logical interface you specify.

### [-count <integer>] - Client Count

Use this parameter to display only logical interfaces with the number of active client connections you specify.

### [-blocked-count <integer>] - (DEPRECATED)-Load Balancing Blocking Count

This parameter has been deprecated and may be removed in a future version of Data ONTAP.

Use this parameter to display information only about data logical interfaces blocked from migrating and the connection that is blocking it.

## Examples

The following example displays information about the servers and logical interfaces being used by all active connections:

```
cluster1::> network connections active show-lifs
Node      Vserver Name  Interface Name  Count
-----
node0
    vs0      datalif1      3
    vs0      cluslif1      6
    vs0      cluslif2      5
node1
```

node2	vs0	datalif2	3
	vs0	cluslif1	3
	vs0	cluslif2	5
node3	vs1	datalif2	1
	vs1	cluslif1	5
	vs1	cluslif2	3
	vs1	datalif1	1
	vs1	cluslif1	2
	vs1	cluslif2	1

At privilege levels above "admin", the command displays an extra column.

```
cluster1::*> network connections active show-lifs
```

Node	Vserver Name	Interface Name	Count	LB Migrate Blocking
node0				
	vs0	datalif1	3	0
	vs0	cluslif1	6	0
	vs0	cluslif2	5	2
node1				
	vs0	datalif2	3	0
	vs0	cluslif1	3	0
	vs0	cluslif2	5	0
node2				
	vs1	datalif2	1	0
	vs1	cluslif1	5	0
	vs1	cluslif2	3	2
node3				
	vs1	datalif1	1	0
	vs1	cluslif1	2	0
	vs1	cluslif2	1	0

## network connections active show-protocols

Show a count of the active connections by protocol

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

### Description

The **network connections active show-protocols** command displays the number of active connections per protocol, organized by node.

The results of this command set are refreshed independently every 30 seconds and might not reflect the immediate state of the system.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[ [-instance ] ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node**

Use this parameter to display information only about the connections on the node you specify.

**[-vserver <vserver>] - Vserver**

This parameter is used by the system to break down the output per vserver.

**[-proto {UDP|TCP}] - Protocol**

Use this parameter to display information only about the connections that use the network protocol you specify. Possible values include tcp (TCP), udp (UDP), and NA (not applicable).

**[-count <integer>] - Client Count**

Use this parameter to display only protocols with the number of active client connections you specify.

## Examples

The following example displays information about all network protocols being used by active connections:

```
cluster1::> network connections active show-protocols
Node      Vserver Name      Protocol  Count
-----  -
node0
  vs1      UDP               19
  vs1      TCP               11
  vs2      UDP               17
node1
  vs1      UDP               14
  vs2      TCP               10
```

# network connections active show-services

Show a count of the active connections by service

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **network connections active show-services** command displays the number of active connections by protocol service, organized by node.

The results of this command set are refreshed independently every 30 seconds and might not reflect the immediate state of the system.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ [-instance ] ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node**

Use this parameter to display information only about the connections on the node you specify.

**[-vserver <vserver>] - Vserver**

This parameter is used by the system to break down the output per vserver

**[-service <protocol service>] - Protocol Service**

Use this parameter to display information only about the connections that use the protocol service you specify. Possible values include: *nfs*, *iscsi*, and *loopback*.

**[-count <integer>] - Client Count**

Use this parameter to display information only about protocol services with the number of active client connections you specify.

## Examples

The following example displays information about all protocol services being used by active connections:

```
cluster1::> network connections active show-services
Node      Vserver Name  Service  Count
```

```

-----
node0

## network connections active show

Show the active connections in this cluster

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

### Description

The **network connections active show** command displays information about active network connections.

The results of this command set are refreshed independently every 30 seconds and might not reflect the immediate state of the system.

### Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ [-print-ip-addresses ] ]**

Print IP addresses for remote hosts — do not attempt to resolve the addresses to a hostname.

**[ [-instance ] ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node**

Selects the connections that match this parameter value.

**[-cid <Cid>] - Connection ID**

Selects the connections that match this parameter value.

**[-vserver <vserver>] - Vserver**

Selects the connections that match this parameter value.

**[-lif-name <lif-name>] - Logical Interface Name**

Selects the connections that match this parameter value.

**[-local-address <IP Address>] - Local IP address**

Selects the connections that match this parameter value.

**[-local-port <integer>] - Local Port**

Selects the connections that match this parameter value.

**[-remote-ip <InetAddress>] - Remote IP Address**

Selects the connections that match this parameter value.

**[-remote-host <Remote IP>] - Remote Host**

Selects the connections that match this parameter value.

**[-remote-port <integer>] - Remote Port**

Selects the connections that match this parameter value.

**[-proto {UDP|TCP}] - Protocol**

Selects the connections that match this parameter value. Possible values are tcp (TCP), udp (UDP), and NA (not applicable).

**[-lifid <integer>] - Logical Interface ID**

Selects the connections that match this parameter value.

**[-service <protocol service>] - Protocol Service**

Selects the connections that match this parameter value. Possible values include: nfs, iscsi, and loopback.

**[-lru {yes|no}] - Least Recently Used**

Selects the connections that match this parameter value.

**[-blocks-lb {true|false}] - Connection Blocks Load Balance Migrate**

Selects the logical interfaces that are blocked (true) or not blocked (false) from migrating due to an active client connection.

## Examples

The following example displays information about active network connections for the node named node0:

```
cluster1::> network connections active show node -node0
```

Vserver Name	Interface Name:Local Port	Remote IP Address:Port	Protocol/Service
node0	cluslif1:7070	192.0.2.253:48621	UDP/rclopcp
node0	cluslif1:7070	192.0.2.253:48622	UDP/rclopcp
node0	cluslif2:7070	192.0.2.252:48644	UDP/rclopcp
node0	cluslif2:7070	192.0.2.250:48646	UDP/rclopcp
node0	cluslif1:7070	192.0.2.245:48621	UDP/rclopcp
node0	cluslif1:7070	192.0.2.245:48622	UDP/rclopcp
node0	cluslif2:7070	192.0.2.251:48644	UDP/rclopcp
node0	cluslif2:7070	192.0.2.251:48646	UDP/rclopcp
node0	cluslif1:7070	192.0.2.248:48621	UDP/rclopcp
node0	cluslif1:7070	192.0.2.246:48622	UDP/rclopcp
node0	cluslif2:7070	192.0.2.252:48644	UDP/rclopcp
node0	cluslif2:7070	192.0.2.250:48646	UDP/rclopcp
node0	cluslif1:7070	192.0.2.254:48621	UDP/rclopcp
node0	cluslif1:7070	192.0.2.253:48622	UDP/rclopcp
[...]			

At privilege levels above "admin", the command displays an extra column.

```
cluster1::*> network connections active show node -node0
```

Vserver Name	Interface Name:Local Port	Remote IP Address:Port	Protocol/Service	Blocks LB Migrate
node0	cluslif1:7070	192.0.2.253:48621	UDP/rclopcp	false
node0	cluslif1:7070	192.0.2.253:48622	UDP/rclopcp	false
node0	cluslif2:7070	192.0.2.252:48644	UDP/rclopcp	false
node0	cluslif2:7070	192.0.2.250:48646	UDP/rclopcp	false
node0	cluslif1:7070	192.0.2.245:48621	UDP/rclopcp	false
node0	cluslif1:7070	192.0.2.245:48622	UDP/rclopcp	false
node0	cluslif2:7070	192.0.2.251:48644	UDP/rclopcp	false
node0	cluslif2:7070	192.0.2.251:48646	UDP/rclopcp	false
node0	cluslif1:7070	192.0.2.248:48621	UDP/rclopcp	false
node0	cluslif1:7070	192.0.2.246:48622	UDP/rclopcp	false
node0	cluslif2:7070	192.0.2.252:48644	UDP/rclopcp	false
node0	cluslif2:7070	192.0.2.250:48646	UDP/rclopcp	false
node0	cluslif1:7070	192.0.2.254:48621	UDP/rclopcp	false
node0	cluslif1:7070	192.0.2.253:48622	UDP/rclopcp	false
[...]				

## network connections listening show

Show the listening connections in this cluster

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **network connections listening show** command displays information about network connections that are in an open and listening state.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[ -node {<nodename>|local} ] - Node**

Selects the listening connections that match this parameter value.

**[ -mgmt-cid <integer> ] - Management Connection ID**

Selects the listening connections that match this parameter value.

**[ -vserver <vserver> ] - Vserver**

Selects the listening connections that match this parameter value.

**[ -cid <integer> ] - System Connection ID**

Selects the listening connections that match this parameter value.

**[ -lif-name <lif-name> ] - Logical Interface Name**

Selects the listening connections that match this parameter value.

**[ -local-address <IP Address> ] - Local IP Address**

Selects the listening connections that match this parameter value.

**[ -local-port <integer> ] - Local Port**

Selects the listening connections that match this parameter value.

**[ -remote-ip <InetAddress> ] - Remote IP Address**

Selects the listening connections that match this parameter value.

**[ -remote-host <Remote IP> ] - Remote Host**

Selects the listening connections that match this parameter value.

**[ -remote-port <integer> ] - Remote Port**

Selects the listening connections that match this parameter value.

**[-proto {UDP|TCP}] - Protocol**

Selects the listening connections that match this parameter value. Possible values include tcp (TCP), udp (UDP), and NA (not applicable).

**[-lifid <integer>] - Logical Interface ID**

Selects the listening connections that match this parameter value.

**[-service <protocol service>] - Protocol Service**

Selects the listening connections that match this parameter value. Possible values include: nfs, iscsi, and loopback.

**[-lru {yes|no}] - Least Recently Used**

Selects the listening connections that match this parameter value.

## Examples

The following example displays information about all listening network connections:

```
cluster1::> network connections listening show
Vserver Name Interface Name:Local Port Protocol/Service
-----
node0        cluslif1:7700          UDP/rclopcp
node0        cluslif2:7700          UDP/rclopcp
node1        cluslif1:7700          UDP/rclopcp
node1        cluslif2:7700          UDP/rclopcp
node2        cluslif1:7700          UDP/rclopcp
node2        cluslif2:7700          UDP/rclopcp
node3        cluslif1:7700          UDP/rclopcp
node3        cluslif2:7700          UDP/rclopcp
8 entries were displayed.
```

The following example displays detailed information about listening network connections for the node named node0:

```
cluster1::> network connections listening show -node node0
Node: node0
Management Connection Id: 0
System Connection Id: 0
Vserver: vs0
Logical Interface Name: datalif1
Local IP address: 192.0.2.130
Local Port: 111
Remote IP address:
Remote Port: 0
Protocol: UDP
Logical Interface Id: 1029
Protocol Service: port_map
```

```
least recently used: yes
  Node: node0
Management Connection Id: 1
  System Connection Id: 0
    Server: vs0
Logical Interface Name: datalif2
  Local IP address: 192.0.2.131
    Local Port: 111
  Remote IP address:
    Remote Port: 0
    Protocol: UDP
Logical Interface Id: 1030
  Protocol Service: port_map
least recently used: yes
```

## network device-discovery show

Display device discovery information

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The network device-discovery show command displays information about discovered devices. This information may be useful in determining the network topology or investigating connectivity issues. By default, the command displays the following information:

- Local interface
- Discovered device
- Discovered interface
- Discovered platform

### Parameters

**{ [-fields <fieldname>,...]**

Include the specified field or fields in the command output. Use '-fields ?' to display the valid fields.

**[-instance ]}**

Use this parameter to display detailed information about all fields.

**[-node <nodename>] - Node**

Displays the discovery ports that match the node name.

**[-protocol {cdp|lldp}] - Protocol**

Displays the devices that are discovered by the given protocol.

**[-port <text>] - Port**

Displays the discovery ports that match the physical network port. For example, e0a will display devices discovered on port e0a.

**[-discovered-device <text>] - Discovered Device**

Displays the discovered devices that match the discovered device name.

**[-interface <text>] - Discovered Device Interface**

Displays the discovered devices that match this interface port name. The format is dependent on the reporting device. For example: FastEthernet0/12

**[-device-ip <IP Address>,...] - Discovered Device IP Addresses**

Displays the discovered devices that match the IP address(es). At present, only IPv4 addresses are included. It is recommended to use wildcards around the desired value.

**[-platform <text>] - Discovered Device Platform**

Displays the discovery ports that contain the platform of discovered devices. For example: N5K-C5010P-BF

**[-version <text>] - Discovered Device Version**

Displays the discovery ports that contain the version of discovered devices.

**[-chassis-id <text>] - Discovered Device Chassis ID**

Displays the discovered devices that match the chassis ID.

**[-system-name <text>] - Discovered Device System Name**

Displays the discovered devices that match the system name.

**[-hold-time-remaining <integer>] - Discovered Device's Remaining Hold Time**

Displays the discovered devices that match the remaining packet hold time in seconds. If an advertisement from the device isn't received before this time reaches zero, the entry will expire and be removed from the list. For example, "<120" will display discovered devices which will expire within the next 120 seconds.

**[-capabilities {router|trans-bridge|source-route-bridge|switch|host|igmp|repeater|phone}] - Discovered Device Capabilities**

Displays the discovered devices that match the capability or capabilities. Possible values:

- "router" - Router
- "trans-bridge" - Trans Bridge
- "source-route-bridge" - Source Route Bridge
- "switch" - Switch
- "host" - Host

- "igmp" - IGMP
- "repeater" - Repeater
- "phone" - Phone

## Examples

```
cluster1::> network device-discovery show
```

Node/ Protocol	Local Port	Discovered Device	Interface	Platform
-----				
node1/cdp				
	e0a	US-LS01-5010-F11-NX.example.com(SSI142311PD)	Ethernet100/1/17	N5K-C5010P-BF

8 entries were displayed.

## network fcp adapter modify

Modify the fcp adapter settings

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

Modifies the FCP target adapter information.

The adapter argument is in the form Xy or Xy\_z where X and z are integers and y is a letter. An example is 4a or 4a\_1.

You cannot bring an adapter offline until all logical interfaces connected to that adapter are offline. Use the [network interface modify](#) command to take your logical interfaces offline.

The speed option sets the Fibre Channel link speed of an adapter. You can set adapters that support:

- 10Gb/s to 10 or auto
- 8Gb/s to 2, 4, 8 or auto
- 4Gb/s to 2, 4 or auto
- 2Gb/s to 2 or auto

By default, the link speed option is set to auto for auto negotiation. Setting the link speed to a specific value disables auto negotiation. Under certain conditions, a speed mismatch can prevent the adapter from coming online.

The system reports the actual link speed with the "Data Link Rate (Gbit)" field in the output of `network fcp adapter show`-instance``.

## Parameters

**-node {<nodename>|local} - Node**

Specifies the node of the target adapter.

**-adapter <text> - Adapter**

Specifies the target adapter.

**[-status-admin {down|up}] - Administrative Status**

Specifies the desired (administrative) status of the adapter. To view the actual operational status, run `network fcp adapter show`-fields`status-oper``.

**[-speed {1|2|4|8|10|16|32|auto}] - Configured Speed**

Specifies the adapter configuration speed in Gigabytes.

## Examples

```
cluster1::> network fcp adapter modify -node node1 -adapter 0d -speed 2
```

Configures the speed of FCP adapter 0d on node1 to 2 Gb/s.

## Related Links

# network fcp adapter show

Display FCP adapters

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Displays FCP target adapter information. You can also use this information to determine if adapters are active and online.

The adapter argument is in the form *Xy* or *Xy\_z* where *X* and *z* are integers and *y* is a letter. An example is *4a* or *4a\_1*.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node**

If this parameter is specified, the command displays information only about the FCP target adapters that are present on the specified node.

**[-adapter <text>] - Adapter**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified name.

**[-description <text>] - Description**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified description.

**[-physical-protocol {fibre-channel|ethernet}] - Physical Protocol**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified physical protocol. Possible values are **fibre-channel** and **ethernet**.

**[-max-speed {1|2|4|8|10|16|32|auto}] - Maximum Speed**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified maximum speed.

**[-status-admin {down|up}] - Administrative Status**

If this parameter is specified, the command displays information only about the FCP target adapters that match the administrative state. Possible values are **up** and **down**.

**[-status-oper <text>] - Operational Status**

If this parameter is specified, the command displays information only about the FCP target

adapters that match the specified operational status.

#### **[-status-extended <text>] - Extended Status**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified extended status.

#### **[-portaddr <Hex Integer>] - Host Port Address**

If this parameter is specified, the command displays information only about the FCP target adapters connected with the specified fabric port address.

#### **[-firmware-rev <text>] - Firmware Revision**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified firmware revision.

#### **[-data-link-rate <integer>] - Data Link Rate (Gbit)**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified data link rate.

#### **[-fabric-established {true|false}] - Fabric Established**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified fabric login establishment state.

#### **[-fabric-name <text>] - Fabric Name**

If this parameter is specified, the command displays information only about the FCP target adapters that are logged in to the fabric with the specified WWN.

#### **[-conn-established {loop|ptp}] - Connection Established**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified connection type. Possible values are **loop** and **ptp**.

#### **[-is-conn-established {true|false}] - Is Connection Established**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified connection established state.

#### **[-media-type {loop|ptp|auto}] - Mediatype**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified configured media type. Possible values are **loop**, **ptp**, and **auto**.

#### **[-speed {1|2|4|8|10|16|32|auto}] - Configured Speed**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified configured speed. If the adapter is set to auto-negotiate, then the value will be **auto**.

#### **[-data-protocols-supported {fcp|fc-nvme}] - Data Protocols Supported**

If this parameter is specified, the command displays information only about the FCP target adapters that may host LIFs with the specified data protocol. Possible values are **fcp** and **fc-nvme**.

**[-domain-id <integer>] - Domain ID**

If this parameter is specified, the command displays information only about the FCP target adapters with a domain identifier that matches the specified domain identifier.

**[-fc-wwnn <text>] - Adapter WWNN**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified world wide node name.

**[-fc-wwpn <text>] - Adapter WWPNN**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified world wide port name.

**[-switch-port <text>] - Switch Port**

If this parameter is specified, the command displays information only about the FCP target adapters that are connected to the specified switch port.

**[-sfp-formfactor <text>] - Form Factor Of Transceiver**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified SFP form factor.

**[-sfp-vendor-name <text>] - Vendor Name Of Transceiver**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified SFP vendor name.

**[-sfp-part-number <text>] - Part Number Of Transceiver**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified SFP part number.

**[-sfp-rev <text>] - Revision Of Transceiver**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified SFP revision number.

**[-sfp-serial-number <text>] - Serial Number Of Transceiver**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified SFP serial number.

**[-sfp-fc-speed-capabilities <text>] - FC Capabilities Of Transceiver**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified SFP speed capabilities.

**[-sfp-vendor-oui <text>] - Vendor OUI Of Transceiver**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified SFP vendor OUI.

**[-sfp-wavelength <integer>] - Wavelength In Nanometers**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified SFP wavelength.

**[-sfp-date-code <text>] - Date Code Of Transceiver**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified SFP date code.

**[-is-sfp-optical-transceiver-valid {true|false}] - Validity Of Transceiver**

If this parameter is specified, the command displays information only about the FCP target adapters that match whether the SFP is installed and valid.

**[-sfp-connector <text>] - Connector Used**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified SFP connector type.

**[-sfp-encoding <text>] - Encoding Used**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified SFP physical encoding.

**[-is-sfp-diagnostics-internally-calibrated {true|false}] - Is Internally Calibrated**

If this parameter is specified, the command displays information only about the FCP target adapters that match whether the SFP diagnostics are internally calibrated or not.

**[-sfp-diagnostic-monitoring-type <Hex Integer>] - Diagnostic Monitoring Type**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified SFP diagnostic monitoring type.

**[-sfp-ddm-capabilities <text>] - Status Monitoring Available**

If this parameter is specified, the command displays information only about the FCP target adapters that match whether the specified SFP digital diagnostics monitoring are supported or not.

**[-sfp-sff8472-compliance <Hex Integer>] - SFF-8472 Compliance**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified SFP SFF8472 compliance.

**[-sfp-rx-power <text>] - Received Optical Power**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified observed SFP receive power.

**[-is-sfp-rx-power-in-range {true|false}] - Is Received Power In Range**

If this parameter is specified, the command displays information only about the FCP target adapters that match whether the observed SFP receive power is within the valid range for the SFP.

**[-sfp-tx-power <text>] - SFP Transmitted Optical Power**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified SFP transmit power.

**[-is-sfp-tx-power-in-range {true|false}] - Is Xmit Power In Range**

If this parameter is specified, the command displays information only about the FCP target adapters that match whether the observed SFP transmit power is within the valid range for the SFP.

**[-sfp-ddm-status-control <Hex Integer>] - DDM Status**

If this parameter is specified, the command displays information only about the FCP target adapters that match the specified SFP DDM status and control.

**[-is-sfp-tx-in-disable {true|false}] - Is Xmit Disabled**

If this parameter is specified, the command displays information only about the FCP target adapters that match whether the observed SFP transmitter is in disabled state.

**[-is-sfp-tx-in-fault {true|false}] - Is Xmit In Fault**

If this parameter is specified, the command displays information only about the FCP target adapters that match whether the observed SFP transmitter is in faulted state.

**[-is-sfp-rx-in-los {true|false}] - Is Receiver In LOS**

If this parameter is specified, the command displays information only about the FCP target adapters that match whether the observed SFP receiver is in loss of signal state.

## Examples

```
cluster1::> fcp adapter show
                Connection Host
Node           Adapter Established Port Address
-----
sti6280-021   0a          ptp          30012c
```

The example above displays information regarding FCP adapters within cluster1.

```
cluster1::> fcp adapter show -instance -node sti6280-021 -adapter 0a
Node: sti6280-021
                Adapter: 0a
                Description: Fibre Channel Target Adapter 0a (QLogic 2532 (2562),
rev. 2, 8G)
                Physical Protocol: fibre-channel
                Maximum Speed: 8
Administrative Status: up
Operational Status: online
Extended Status: ADAPTER UP
Host Port Address: 30012c
Firmware Revision: 5.8.0
Data Link Rate (Gbit): 4
Fabric Established: true
                Fabric Name: 20:14:54:7f:ee:54:b9:01
Connection Established: ptp
```

```
Is Connection Established: true
    Mediatype: ptp
    Configured Speed: auto
    Adapter WWNN: 50:0a:09:80:8f:7f:8b:1c
    Adapter WWPN: 50:0a:09:81:8f:7f:8b:1c
    Switch Port: RTP-AG01-410B51:1/41
Form Factor Of Transceiver: SFP
Vendor Name Of Transceiver: OPNEX,INC
Part Number Of Transceiver: TRS2000EN-SC01
    Revision Of Transceiver: 0000
Serial Number Of Transceiver: T10H64793
FC Capabilities Of Transceiver: 10 (Gbit/sec)
    Vendor OUI Of Transceiver: 0:11:64
    Wavelength In Nanometers: 850

The example above displays detailed information regarding FCP adapter 0a in sti6280-021 within cluster1.

## network fcp topology show

FCP topology interconnect elements per adapter

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

Display FCP topology interconnect elements per adapter.

### Parameters

**{ [-fields <fieldname>,...]**

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[-instance ]}**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node**

Use this parameter to select the interconnect elements for adapters that are located on the node that you specify.

**[-adapter <text>] - Adapter**

Use this parameter to select the interconnect elements for the specified adapter.

**[-domain-id <integer>] - Domain Id**

Use this parameter to select the interconnect elements with the specified domain identifier.

**[-port-wwpn <text>] - Port WWPN**

Use this parameter to select the interconnect elements with the specified port world wide name.

**[-switch-name <text>] - Switch Name**

Use this parameter to select the interconnect elements with the specified switch.

**[-switch-vendor <text>] - Switch Vendor**

Use this parameter to select the interconnect elements with the specified vendor.

**[-switch-release <text>] - Switch Release**

Use this parameter to select the interconnect elements with the specified release.

**[-switch-wwpn <text>] - Switch WWPN**

Use this parameter to select the interconnect elements with the specified world wide port name.

**[-switch-wwn <text>] - Switch WWN**

Use this parameter to select the interconnect elements with the specified world wide name.

**[-port-count <integer>] - Port Count**

Use this parameter to select the interconnect elements with the specified port count.

**[-port-slot <text>] - Port Slot**

Use this parameter to select the interconnect elements with the specified port slot.

**[-port-state {Unknown|Online|Offline|Testing|Fault}] - Port State**

Use this parameter to select the interconnect elements with the specified port state.

**[-port-type {None|N-Port|NL-Port|FNL-Port|NX-Port|F-Port|FL-Port|E-Port|B-Port|TNP-Port|TF-Port|NV-Port|FV-Port|SD-Port|TE-Port|TL-Port}] - Port Type**

Use this parameter to select the interconnect elements with the specified port type.

**[-port-attached-wwpn <text>] - Attached Port WWPN**

Use this parameter to select the interconnect elements with the specified attached wwpn.

**[-port-attached-id <text>] - Attached Port Id**

Use this parameter to select the interconnect elements with the specified attached id.

**[-port-attached-visible <text>] - Visible**

Use this parameter to select the interconnect elements with the specified visibility flag on attached port structure.

## Examples

```

# network fcp zone show

Display the active zone set information

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Displays the active zone set information.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node**

Use this parameter to select the active zone set information for adapters that located on the node name that you specify.

**[-adapter <text>] - Adapter**

Use this parameter to select the active zone set information for the specified adapter.

**[-zoneset-name <text>] - Zoneset Name**

Use this parameter to select the active zone set information for the specified zone set name.

**[-zone-name <text>] - Zone Name**

Use this parameter to select the active zone set information for the specified zone name.

**[-type-name <text>] - Type Name**

Use this parameter to select the active zone set information with the specified symbolic type.

**[-type <integer>] - Type**

Use this parameter to select the active zone set information with the specified port type.

**[-port-id <Hex Integer>] - Member Port Id**

Use this parameter to select the active zone set information with the specified member port id.

**[-domain-id <integer>] - Member Domain Id**

Use this parameter to select the active zone set information with the specified member domain id.

**[-port <integer>] - Member Port**

Use this parameter to select the active zone set information with the specified member port.

**[-wwn <text>] - Member WWN**

Use this parameter to select the active zone set information with the specified member WWN.

**[-zone-count <integer>] - Zone Count**

Use this parameter to select the active zone set information with the specified number of zones.

**[-zone-member-count <integer>] - Zone Member Count**

Use this parameter to select the active zone set information with the specified number of zone members in a zone.

**[-contents <text>] - Member Contents**

Use this parameter to select the active zone set information using any type.

## Examples

```
cluster1::> network fcp adapter zone show
```

Zone Name	Member Type	WWN
-----		
Active Zone Set on adapter 0c		
Zone Set Name: zoneset_name		
zone_name_1	Port ID	-
zone_name_1	Port ID	-
zone_name_1	Port ID	-
zone_name_2	Domain ID/Port	-
zone_name_2	Domain ID/Port	-
zone_name_2	Domain ID/Port	-
zone_name_3	Fabric Port Name	00:00:00:00:00:00:00:00
zone_name_3	Fabric Port Name	01:00:00:00:00:00:00:00
zone_name_3	Fabric Port Name	02:00:00:00:00:00:00:00

9 entries were displayed.

The example above displays information regarding active zone set information for the cluster.

## network interface create

Create a logical interface

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **network interface create** command creates a logical interface (LIF).

A logical interface is an IP address associated with a physical network port. For logical interfaces using NAS data protocols, the interface can fail over or be migrated to a different physical port in the event of component failures, thereby continuing to provide network access despite the component failure.

On some cloud platforms, this operation might perform changes to the external route tables.

## Parameters

### **-vserver <vserver> - Vserver Name**

Use this parameter to specify the Vserver on which the LIF is created.

### **-lif <lif-name> - Logical Interface Name**

Use this parameter to specify the name of the LIF that is created. For iSCSI and FC LIFs, the name cannot be more than 254 characters.

### **[-service-policy <text>] - Service Policy**

Use this parameter to specify a service policy for the LIF. If no policy is specified, a default policy will be assigned automatically. Use the [network interface service-policy show](#) command to review available service policies.

### **[-role {undef|cluster|data|node-mgmt|intercluster|cluster-mgmt}] - (DEPRECATED)-Role**

This parameter has been deprecated and may be removed in a future version of ONTAP. Use the **-service-policy** parameter instead.

Use this parameter to specify the role of the LIF. LIFs can have one of five roles:

- Cluster LIFs, which provide communication among the nodes in a cluster
- Intercluster LIFs, which provide communication among peered clusters
- Data LIFs, which provide data access to NAS and SAN clients
- Node-management LIFs, which provide access to cluster management functionality
- Cluster-management LIFs, which provide access to cluster management functionality

LIFs with the cluster-management role behave as LIFs with the node-management role except that cluster-management LIFs can failover between nodes.

### **[-data-protocol {nfs|cifs|iscsi|fcp|fcache|none|fc-nvme|s3|nvme-tcp}] - Data Protocol**

Use this parameter to specify the list of data protocols that can be served by the LIF. The supported protocols are NFS, CIFS, iSCSI, FCP, and FC-NVMe. NFS and CIFS are available by default when you create a LIF. If you specify "none", the LIF does not support any data protocols. Also, none, iscsi, fcp or fc-nvme cannot be combined with any other protocols.

The data-protocol field must be specified when the LIF is created and cannot be modified later.

The NFS protocol relies on firewall services included in the built-in "data" and "mgmt-nfs" firewall policies. Assigning a different firewall policy might disrupt some NFS client implementations.

#### **-address <IP Address> - Network Address**

Use this parameter to specify the LIF's IP address.

A cluster LIF cannot be on the same subnet as a management or data LIF.

#### **{ -netmask <IP Address> - Netmask**

Use this parameter to specify the LIF's netmask.

#### **| -netmask-length <integer> - Bits in the Netmask**

Use this parameter to specify the length (in bits) of the LIF's netmask.

#### **| -is-vip <true> - Is VIP LIF**

Use this parameter to display only logical interfaces matching a specify "is-vip" flag. Specifying "true" matches only LIFs to implement a Virtual IP; "false" matches only LIFs that do not.

#### **{ [-auto <true>] - Allocate Link Local IPv4 Address**

Use this parameter to specify whether IPv4 link local addressing is enabled for this LIF.

#### **| [-subnet-name <subnet name>] - Subnet Name }**

Use this parameter to allocate the interface address from a subnet. If needed, a default route will be created for this subnet.

#### **[-home-node <nodename>] - Home Node**

Use this parameter to specify the LIF's home node. The home node is the node to which the LIF returns when the network interface revert command is run on the LIF.

#### **[-home-port {<netport>|<ifgrp>}] - Home Port**

Use this parameter to specify the LIF's home port or interface group. The home port is the port or interface group to which the LIF returns when the network interface revert command is run on the LIF.

#### **[-status-admin {up|down}] - Administrative Status**

Use this parameter to specify whether the initial administrative status of the LIF is up or down. The default setting is **up**. The administrative status can differ from the operational status. For example, if you specify the status as up but a network problem prevents the interface from functioning, the operational status remains as down.

#### **[-failover-policy {system-defined|local-only|sfo-partner-only|disabled|broadcast-domain-wide}] - Failover Policy**

Use this parameter to specify the failover policy for the LIF.

- **system-defined** - The system determines appropriate failover targets for the LIF. The default behavior is that failover targets are chosen from the LIF's current hosting node and also from one other non-partner node when possible.
- **local-only** - The LIF fails over to a port on the local or home node of the LIF.
- **sfo-partner-only** - The LIF fails over to a port on the home node or SFO partner only.
- **broadcast-domain-wide** - The LIF fails over to a port in the same broadcast domain as the home port.
- **disabled** - Failover is disabled for the LIF.

The failover policy for cluster logical interfaces is **local-only** and cannot be changed. The default failover policy for data logical interfaces is **system-defined**. This value can be changed.

### **[-firewall-policy <policy>] - (DEPRECATED)-Firewall Policy**

This parameter has been deprecated and may be removed in a future version of ONTAP. Use the **-service-policy** parameter instead.

Use this parameter to specify the firewall policy for the LIF. A LIF can use a default firewall policy that corresponds to its role (management, cluster, intercluster, or data) or a custom firewall policy created by an administrator. View and modify existing firewall policies using the [system services firewall policy show](#) and [system services firewall policy modify](#) commands, respectively.

The NFS data protocol relies on firewall services included in the built-in "data" and "mgmt-nfs" firewall policies. Assigning a different firewall policy might disrupt some NFS client implementations.

### **[-auto-revert {true|false}] - Auto Revert**

Use this parameter to specify whether a data LIF is automatically reverted to its home port under certain circumstances. These circumstances include startup, when the status of the management database changes to either master or secondary, or when the network connection is made.

### **[-dns-zone {<zone-name>|none}] - Fully Qualified DNS Zone Name**

Use this parameter to specify a unique, fully qualified domain name of a DNS zone to which this data LIF is added. You can associate a data LIF with a single DNS zone. All data LIFs included in a zone must be on the same Vserver. If a LIF is not added to a DNS zone the data LIF is created with the value **none**.

### **[-listen-for-dns-query {true|false}] - DNS Query Listen Enable**

Use this parameter to specify if the LIF has to listen for DNS queries. The default value for this parameter is **true**.

### **[-allow-lb-migrate {true|false}] - (DEPRECATED)-Load Balancing Migrate Allowed**

This parameter has been deprecated and may be removed in a future version of Data ONTAP.

Use this parameter to specify whether load balancing migration is activated for this data LIF. The default value of this parameter is **false**. If you set the value of this parameter to **true**, automatic

revert capability for this data LIF is disabled (the **-auto-revert** parameter is set to **false** ). Also, data LIFs that migrate as a result of load balancing adhere to network interface failover rules.

During times when a LIF is hosting active NFSv4, CIFS, or NRV connections, load balancing based LIF migrations between nodes will be temporarily disabled.

### **[-lb-weight {load|0..100}] - Load Balanced Weight**

Use this parameter to specify a load balancing weight for a data LIF. A valid numeric load balancing weight is any integer between 0 and 100. When you specify the same load balancing weight for all data LIFs in a DNS zone, client requests are uniformly distributed, similar to round-robin DNS. A data LIF with a low load balancing weight is made available for client requests less frequently than one that has a high load balancing weight. "load" is the default value of this parameter. If set to "load", node utilization statistics are used to dynamically assign the load balancing weight.

### **[-failover-group <failover-group>] - Failover Group Name**

Use this parameter to specify the name of the failover group to associate with the LIF. Manage failover groups by using the **network interface failover-groups** command. Each broadcast domain has a default failover group which is created by the system automatically and has the same name as the broadcast domain. The failover group associated with the broadcast domain includes all ports in the broadcast domain. A logical interface's failover group is set to the failover group of the home port's broadcast domain by default, but this value can be modified.

### **[-comment <text>] - Comment**

Use this parameter to specify the comment to associate with the LIF.

### **[-force-subnet-association <>true>] - Force the LIF's Subnet Association**

This command will fail if the IP address falls within the address range of a named subnet. Set this to true to acquire the address from the named subnet and assign the subnet to the LIF.

### **[-is-dns-update-enabled {true|false}] - Is Dynamic DNS Update Enabled?**

If this parameter is set to **true** , then dynamic DNS update is sent to the DNS server for the particular LIF entry if dynamic DNS updates are enabled for the corresponding Vserver. This field is set to **true** by default for both IPv4 and IPv6 LIFs. DNS Update is not supported on LIFs not configured with either the NFS or CIFS protocol.

### **[-probe-port <integer>] - Probe-port for Cloud Load Balancer**

Use this parameter to specify a probe-port for the LIF in the Azure environment. It is a required field in the Azure environment. If no probe-port is specified, an error would be returned.

### **[-broadcast-domain <text>] - Broadcast Domain**

Use this parameter to display the broadcast domain that contains the home port of the logical interface.

### **[-rdma-protocols <roce>, ...] - Required RDMA offload protocols**

Defines RDMA offload protocols required by the LIF. A non-empty list will ensure that this LIF can only be moved to network ports that support the specified RDMA offload protocols.

## Examples

The following example creates an IPv4 LIF named `datlif1` and an IPv6 LIF named `datlif2` on a Vserver named `vs0`. Their home node is `node0` and home port is `e0c`. The failover policy **broadcast-domain-wide** is assigned to both LIFs. The service policy is **default-data-files** and the LIFs are automatically reverted to their home node at startup and under other circumstances. The `datlif1` has the IP address `192.0.2.130` and netmask `255.255.255.128`, and `datlif2` has the IP address `3ffe:1::aaaa` and netmask length of `64`.

```
cluster1::> network interface create -vserver vs0 -lif datlif1 -home-node node0 -home
-port e0c -address 192.0.2.130 -netmask 255.255.255.128 -failover-policy broadcast-
domain-wide -service-policy default-data--files -auto-revert true
cluster1::> network interface create -vserver vs0 -lif datlif2 -home-node node0 -home
-port e0c -address 3ffe:1::aaaa -netmask-length 64 -failover-policy broadcast-domain-
wide -service-policy default-data-files -auto-revert true
```

- [system services firewall policy show](#)
- [system services firewall policy modify](#)

# network interface delete

Delete a logical interface

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **network interface delete** command deletes a logical interface (LIF) from a Vserver. Only administratively down LIFs can be deleted. To make a LIF administratively down, use the [network interface modify](#) command to set the "status-admin" parameter to "down".

If the LIF is configured for a SAN protocol and is part of a portset, the LIF must be removed from the portset before it can be deleted. To determine if a LIF is in a portset, use the [lun portset show](#) command. To remove the LIF from the portset, use the [lun portset remove](#) command.

On some cloud platforms, this operation might perform changes to the external route tables.

## Parameters

### **-vserver <vserver> - Vserver Name**

Use this parameter to specify the Vserver on which the logical interface to be deleted is located.

### **-lif <lif-name> - Logical Interface Name**

Use this parameter to specify the logical interface to delete.

## Examples

The following example deletes a logical interface named cluslif3 that is located on a Vserver named vs0.

```
cluster1::> network interface delete -vserver vs0 -lif cluslif3
```

## Related Links

- [network interface modify](#)
- [lun portset show](#)
- [lun portset remove](#)

# network interface migrate-all

Migrate all data logical interfaces away from the specified node

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **network interface migrate-all** command migrates all data logical interfaces from the node you specify.

Manual migration of a logical interface can take up to 15 seconds to complete. Logical interface migration is a best-effort command and can only be completed if the destination node and port are operational. Logical interface migration requires that the logical interface be pre-configured with valid failover rules to facilitate failover to a remote node.

On some cloud platforms, this operation might perform changes to the external route tables.

## Parameters

### **-node <nodename> - Node**

Use this parameter to specify the node from which all logical interfaces are migrated. Each data logical interface is migrated to another node in the cluster, assuming that the logical interface is configured with failover rules that specify an operational node and port.

### **[-port {<netport>|<ifgrp>}] - Port**

Use this parameter to specify the port from which all logical interfaces are migrated. This option cannot be used with asynchronous migrations. If this parameter is not specified, then logical interfaces will be migrated away from all ports on the specified node.

## Examples

The following example migrates all data logical interfaces from the current (local) node.

```
cluster1::> network interface migrate-all -node local
```

# network interface migrate

Migrate a logical interface to a different port

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **network interface migrate** command migrates a logical interface to a port or interface group on the node you specify.

Manual migration of a logical interface can take up to 15 seconds to complete. Also, when you migrate a cluster logical interface, you must do so from the local node. Logical interface migration is a best-effort command, and can only be completed if the destination node and port are operational

On some cloud platforms, this operation might perform changes to the external route tables.

## Parameters

### **-vserver <vserver> - Vserver Name**

Use this parameter to specify the Vserver that owns the logical interface that is to be migrated.

### **-lif <lif-name> - Logical Interface Name**

Use this parameter to specify the logical interface that is to be migrated.

**-destination-node <nodename> - Destination Node**

Use this parameter to specify the node to which the logical interface is to be migrated.

**[-destination-port {<netport>|<ifgrp>}] - Destination Port**

Use this parameter to specify the port or interface group to which the logical interface is to be migrated.

**[-force <>true>] - Force Migrate Data LIF Flag**

Use this parameter to force the migration operation. Intended for disaster recovery only. Specifying this parameter implies the LIF's current node is down and will skip removing the LIF from its current node.

## Examples

The following example migrates a logical interface named `datalif1` on a Vserver named `vs0` to port `e0c` on a node named `node2`:

```
cluster1::> network interface migrate -vserver vs0 -lif datalif1 -dest-node node2  
-dest-port e0c
```

# network interface modify

Modify a logical interface

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `network interface modify` command modifies attributes of a logical interface (LIF).

You cannot modify some properties of an iSCSI or FCP LIF, such as `-home-node` or `-home-port`, if the LIF is in a portset. To modify these properties, first remove the LIF from the portset. To determine if a LIF is in a portset, use the [lun portset show](#) command. To remove the LIF from the portset, use the [lun portset remove](#) command.

On some cloud platforms, this operation might perform changes to the external route tables.

## Parameters

**-vserver <vserver> - Vserver Name**

Use this parameter to specify the Vserver on which the LIF to be modified is located.

**-lif <lif-name> - Logical Interface Name**

Use this parameter to specify the name of the LIF that is to be modified

**[-service-policy <text>] - Service Policy**

Use this parameter to modify the service policy associated with the LIF.

**[-address <IP Address>] - Network Address**

Use this parameter to modify the LIF's IP address.

A cluster LIF cannot be on the same subnet as a data or management LIF.

**{ [-netmask <IP Address>] - Netmask**

Use this parameter to modify the LIF's netmask.

**| [-netmask-length <integer>] - Bits in the Netmask**

Use this parameter to modify the length (in bits) of the LIF's netmask.

**| [-subnet-name <subnet name>] - Subnet Name }**

Use this parameter to allocate the interface address from a subnet. Modifying this parameter will cause a new IP address to be allocated and assigned to the interface.

**[-home-node <nodename>] - Home Node**

Use this parameter to modify the LIF's home node. The home node is the node to which the LIF returns when the [network interface revert](#) command is run on that LIF.

**[-home-port {<netport>|<ifgrp>}] - Home Port**

Use this parameter to modify the LIF's home port. The home port is the port or interface group to which the LIF returns when the [network interface revert](#) command is run on that LIF.

If you change this parameter for a cluster or management LIF, you must reboot the storage system to force the change to take effect.

**[-status-admin {up|down}] - Administrative Status**

Use this parameter to modify the administrative status of the LIF. The administrative status can differ from the operational status. For example, if you specify the status as **up** but a network problem prevents the interface from functioning, the operational status remains as **down**.

**[-failover-policy {system-defined|local-only|sfo-partner-only|disabled|broadcast-domain-wide}] - Failover Policy**

Use this parameter to modify the failover policy for the LIF.

- **system-defined** - The system determines appropriate failover targets for the LIF. The default behavior is that failover targets are chosen from the LIF's current hosting node and also from one other non-partner node when possible.
- **local-only** - The LIF fails over to a port on the local or home node of the LIF.
- **sfo-partner-only** - The LIF fails over to a port on the home node or SFO partner only.
- **broadcast-domain-wide** - The LIF fails over to a port in the same broadcast domain as the

home port.

- disabled - Failover is disabled for the LIF.

The failover policy for cluster logical interfaces is local-only and cannot be changed. The default failover policy for data logical interfaces is system-defined. This value can be changed.

### **[-firewall-policy <policy>] - (DEPRECATED)-Firewall Policy**

This parameter has been deprecated and may be removed in a future version of ONTAP. Use the **-service-policy** parameter instead.

Use this parameter to set the firewall policy for the LIF. A LIF can use a default firewall policy that corresponds to its role (management, cluster, or data) or a custom firewall policy created by an administrator. When using a custom policy, the interface will fallback on its role's default policy for unspecified services. View existing firewall policies with the "system services firewall policy show" command. Modify existing firewall policies with the "system services firewall policy modify" command.

The NFS data protocol relies on firewall services included in the built-in "data" and "mgmt-nfs" firewall policies. Assigning a different firewall policy might disrupt some NFS client implementations.

### **[-auto-revert {true|false}] - Auto Revert**

Use this parameter to modify whether a data LIF is reverted automatically to its home port under certain circumstances. These circumstances would include startup, when the status of the management database changes to either master or secondary, and when the network connection is made.

### **[-dns-zone {<zone-name>|none}] - Fully Qualified DNS Zone Name**

Use this parameter to modify the unique, fully qualified domain name of the DNS zone to which this data LIF belongs. You can associate a data LIF with a single DNS zone. All data LIFs included in a zone must be on the same Vserver. If you do not specify a value for this parameter, the data LIF is created with the value **none**.

### **[-listen-for-dns-query {true|false}] - DNS Query Listen Enable**

Use this parameter to specify if the LIF has to listen for DNS queries. The default value for this parameter is true.

### **[-allow-lb-migrate {true|false}] - (DEPRECATED)-Load Balancing Migrate Allowed**

This parameter has been deprecated and may be removed in a future version of Data ONTAP.

Use this parameter to modify whether or not load balancing migration is enabled for this data LIF. The default value of this parameter is **false**. If you set the value of this parameter to **true**, the automatic revert capability of the data LIF is disabled (the **-auto-revert** parameter is set to **false**). Also, data LIFs that migrate as a result of load balancing adhere to network interface failover rules.

During times when a LIF is hosting active NFSv4, CIFS, or NRV connections, load balancing based LIF migrations between nodes will be temporarily disabled.

### **[-lb-weight {load|0..100}] - Load Balanced Weight**

Use this parameter to modify the load balancing weight of the data LIF. A valid load balancing weight is any integer between 1 and 100. If you specify the same load balancing weight for all data LIFs in a DNS zone, client requests are uniformly distributed, similar to round-robin DNS. A data LIF with a low load balancing weight is made available for client requests less frequently than one that has a high load balancing weight.

### **[-failover-group <failover-group>] - Failover Group Name**

Use this parameter to modify the name of the failover group to associate with the network interface. Manage failover groups using the **network interface failover-groups** command. Each broadcast domain has a default failover group which is created by the system automatically and has the same name as the broadcast domain. The failover group associated with the broadcast domain includes all ports in the broadcast domain. A logical interface's failover group is set to the failover group of the home port's broadcast domain by default, but this value can be modified.

### **[-comment <text>] - Comment**

Use this parameter to modify the comment associated with the LIF.

### **[-force-subnet-association <true>] - Force the LIF's Subnet Association**

This command will fail if the IP address falls within the address range of a named subnet. Set this to true to acquire the address from the named subnet and assign the subnet to the LIF.

### **[-is-dns-update-enabled {true|false}] - Is Dynamic DNS Update Enabled?**

If this parameter is set to **true**, then dynamic DNS update is sent to the DNS server for the particular LIF entry if dynamic DNS updates are enabled for the corresponding Vserver. This field is set to **true** by default for both IPv4 and IPv6 LIFs. DNS Update is not supported on LIFs not configured with either the NFS or CIFS protocol.

### **[-rdma-protocols <roce>, ...] - Required RDMA offload protocols**

Defines RDMA offload protocols required by the LIF. A non-empty list will ensure that this LIF can only be moved to network ports that support the specified RDMA offload protocols.

## Examples

The following example modifies a LIF named `datalif1` on a logical server named `vs0`. The LIF's netmask is modified to `255.255.255.128`.

```
cluster1::> network interface modify -vserver vs0 -lif datalif1 -netmask
255.255.255.128
```

## network interface rename

Rename a logical interface

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

Use the `network interface rename` command to change the name of an existing logical interface.

### Parameters

**-vserver <vserver> - Vserver Name**

Use this parameter to specify the Vserver on which the logical interface to rename is located.

**-lif <lif-name> - Logical Interface Name**

Use this parameter to specify the name of the logical interface to rename.

**-newname <text> - The new name for the interface**

Use this parameter to specify the new name of the logical interface. For iSCSI and FC LIFs, the name cannot be more than 254 characters.

### Examples

The following example renames a cluster logical interface named `cluslif1` to `cluslif4` on a Vserver named `vs0`.

```
cluster1::> network interface rename -vserver vs0 -lif cluslif1 -newname cluslif4
```

## network interface revert

Revert a logical interface to its home port

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **network interface revert** command reverts a logical interface that is not currently on its home port to its home port, assuming that the home node and port are both operational. A logical interface's home port is specified when the logical interface is created. Determine a logical interface's home port by using the [network interface show](#) command.

When you revert a cluster logical interface, you must do so from the local node.

On some cloud platforms, this operation might perform changes to the external route tables.

## Parameters

### **-vserver <vserver> - Vserver Name**

Use this parameter to specify the Vserver on which the logical interface to be reverted is located.

### **-lif <lif-name> - Logical Interface Name**

Use this parameter to specify the logical interface that is to be reverted.

Logical interfaces for SAN protocols are always home. Thus, this command has no effect on such interfaces. The same applies to logical interfaces for NAS protocols that are already home.

## Examples

The following example returns any logical interfaces that are not currently on their home ports to their home ports.

```
cluster1::> network interface revert -vserver * -lif *
```

# network interface show

Display logical interfaces

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **network interface show** command displays information about logical interfaces.

Running the command with the **-failover** parameter displays information relevant to logical interface failover rules.

Running the command with the **-status** parameter displays information relevant to logical interface operational status.

Running the command with the **-by-ip-space** parameter displays information relevant to logical interfaces on a specific IPspace.

See the examples for more information.

You can specify additional parameters to display only information that matches those parameters. For example, to display information only about logical interfaces whose operational status is down, run the command with the **-status-oper down** parameter.

## Parameters

**{ [-fields <fieldname>, ... ]**

If you specify the **-fields <fieldname>, ...** parameter, the command displays only the fields that you specify.

**| [-by-ip-space ]**

Use this parameter to display logical-interfaces sorted by IPspace and Vserver.

**| [-dns-zones ]**

Use this parameter to display logical-interfaces and whether the interface is associated with a Domain Name System (DNS) load balancing zone.

**| [-failover ]**

Use this parameter to display logical-interface failover information.

**| [-status ]**

Use this parameter to display detailed logical-interface status information.

**| [-instance ] }**

Use this parameter to display all the fields for the specified logical-interfaces.

**[-vserver <vserver>] - Vserver Name**

Use this parameter to display information only about logical interfaces on the Vserver you specify.

Use this parameter plus the **-lif** parameter to display detailed information only about the logical interface you specify.

**[-lif <lif-name>] - Logical Interface Name**

Use this parameter to display information only about logical interfaces that match the name you specify.

Use this parameter with the **-vserver** parameter to display detailed information only about the logical interface you specify.

**[-service-policy <text>] - Service Policy**

Use this parameter to display information only about logical interfaces that have the service policy you specify.

**[-services <LIF Service Name>,...] - Service List**

Use this parameter to display information only about logical interfaces that support all services in a comma-separated list of service names.

**[-role {undef|cluster|data|node-mgmt|intercluster|cluster-mgmt}] - (DEPRECATED)-Role**

This parameter has been deprecated and may be removed in a future version of ONTAP. Use either the **-service-policy** or **-services** parameter instead.

Use this parameter to display information only about logical interfaces that are associated with network ports that have the role you specify.

**[-data-protocol {nfs|cifs|iscsi|fcp|fcache|none|fc-nvme|s3|nvme-tcp}] - Data Protocol**

Use this parameter to display information only about logical interfaces that have the enabled data protocols you specify.

**[-address <IP Address>] - Network Address**

Use this parameter to display information only about logical interfaces that match the IP address or address range you specify.

**[-netmask <IP Address>] - Netmask**

Use this parameter to display information only about logical interfaces that have the netmask you specify.

**[-netmask-length <integer>] - Bits in the Netmask**

Use this parameter to display information only about logical interfaces with a netmask that has the number of bits you specify.

**[-is-vip <>true>] - Is VIP LIF**

Use this parameter to display information only about logical interfaces that are VIP LIFs or not as you specify.

**[-subnet-name <subnet name>] - Subnet Name**

Use this parameter to display the logical interfaces that matches the subnet name.

**[-home-node <nodename>] - Home Node**

Use this parameter to display information only about logical interfaces that have the home node you specify.

**[-home-port {<netport>|<ifgrp>}] - Home Port**

Use this parameter to display information only about logical interfaces that have the home port or interface group you specify.

**[-curr-node <nodename>] - Current Node**

Use this parameter to display information only about logical interfaces that are currently located on the node you specify.

**[-curr-port {<netport>|<ifgrp>}] - Current Port**

Use this parameter to display information only about logical interfaces that are currently located on the port or interface group you specify.

**[-status-oper {up|down}] - Operational Status**

Use this parameter to display information only about logical interfaces that have the operational status you specify.

**[-status-extended <text>] - Extended Status**

Use this parameter to display information only about logical interfaces that match the extended status that you specify.

**[-numeric-id <integer>] - Numeric ID**

Use this parameter to display information only about logical interfaces with the numeric ID (or range of IDs) you specify. The numeric ID is an integer that identifies the logical interface in the cluster.

**[-is-home {true|false}] - Is Home**

Use this parameter to display information only about logical interfaces that are (true) or are not (false) currently located on their home node and port.

**[-status-admin {up|down}] - Administrative Status**

Use this parameter to display information only about logical interfaces that have the administrative status you specify.

**[-failover-policy {system-defined|local-only|sfo-partner-only|disabled|broadcast-domain-wide}]****- Failover Policy**

Use this parameter to display information only about logical interfaces that use the failover policy you specify.

**[-firewall-policy <policy>] - (DEPRECATED)-Firewall Policy**

This parameter has been deprecated and may be removed in a future version of ONTAP. Use the **-service-policy** parameter instead.

Use this parameter to display information only about logical interfaces that use the firewall policies you specify.

**[-auto-revert {true|false}] - Auto Revert**

Use this parameter to display information only about logical interfaces that have auto-revert setting you specify.

**[-sticky {true|false}] - Sticky Flag**

Use this parameter to display information only about logical interfaces that are "sticky". A sticky logical interface is one that has been manually migrated to another node and is not subject to auto-revert settings. A sticky logical interface remains at the migrated location until it is manually reverted or until it fails over to another node.

**[-dns-zone {<zone-name>|none}] - Fully Qualified DNS Zone Name**

Use this parameter to display information only about logical interfaces in the specified DNS zone.

**[-listen-for-dns-query {true|false}] - DNS Query Listen Enable**

Use this parameter to display information only about logical interfaces that have the DNS query listen value you specify.

**[-allow-lb-migrate {true|false}] - (DEPRECATED)-Load Balancing Migrate Allowed**

This parameter has been deprecated and may be removed in a future version of Data ONTAP.

Use this parameter to display information only about logical interfaces for which load balancing migration is activated (true) or not activated (false).

**[-lb-weight {load|0..100}] - Load Balanced Weight**

Use this parameter to display information only about logical interfaces that have the load balancing weight you specify.

**[-failover-group <failover-group>] - Failover Group Name**

Use this parameter to display information only about logical interfaces that are in the failover group you specify. Logical interfaces in the same failover group are capable of failing over to the same set of ports.

**[-wwpn <text>] - FCP WWPN**

Use this parameter to display information only about logical interfaces that have the Fibre Channel Protocol port identifier (World Wide Port Name) you specify.

**[-address-family {ipv4|ipv6|ipv6z}] - Address family**

Use this parameter to view the address family that is in use on the interface. Only IPv4 and IPv6 non-zoned addresses can be configured. Configuration of IPv6z addresses is not allowed.

**[-comment <text>] - Comment**

Use this parameter to display information only about logical interfaces that have the comment you specify.

**[-ipSPACE <IPspace>] - IPspace of LIF**

Use this parameter to display information only about logical interfaces on the IPspace you specify.

**[-is-dns-update-enabled {true|false}] - Is Dynamic DNS Update Enabled?**

Use this parameter to display information only about logical interfaces that have (true) or do not have (false) dynamic DNS updates enabled for them.

**[-probe-port <integer>] - Probe-port for Cloud Load Balancer**

Use this parameter display the probe-port for the logical interface in the Azure environment.

**[-broadcast-domain <text>] - Broadcast Domain**

Use this parameter to display the broadcast domain that contains the home port of the logical interface.

**[-vserver-type <vserver type>] - Vserver Type**

Use this parameter to display information only about logical interfaces owned by Vservers of the specified type.

**[-rdma-protocols <roce>, ...] - Required RDMA offload protocols**

Use this parameter to display the logical interfaces associated with one or more RDMA protocols.

## Examples

The following example displays general information about all logical interfaces.

```
cluster1::> network interface show
```

Vserver	Logical Interface	Status Admin/Oper	Network Address/Mask	Current Node	Current Port	Is Home
-----						
cluster1	cluster_mgmt	up/up	192.0.2.1/192	node0	e0M	true
	node0_mgmt1	up/up	192.0.2.2/192	node0	e0M	true
	node1_mgmt1	up/up	192.0.2.3/192	node1	e0M	true
Cluster	node0_clus1	up/up	192.0.2.66/192	node0	e0a	true
	node0_clus2	up/up	192.0.2.67/192	node0	e0b	true
	node1_clus1	up/up	192.0.2.68/192	node1	e0a	true
	node1_clus2	up/up	192.0.2.69/192	node1	e0b	true

The following example displays failover information about all logical interfaces.

```
cluster1::> network interface show -failover
```

Vserver	Logical Interface	Home Node:Port	Failover Policy	Failover Group
-----				
cluster1	cluster_mgmt	node0:e0M	broadcast-domain-wide	

			Default
	Failover Targets:	node0:e0M, node0:e0d, node0:e0e, node0:e0f, node1:e0M, node1:e0d, node1:e0e, node1:e0f	
node0_mgmt1	node0:e0M	local-only	Default
	Failover Targets:	node0:e0M, node0:e0d, node0:e0e, node0:e0f	
node1_mgmt1	node1:e0M	local-only	Default
	Failover Targets:	node1:e0M, node1:e0d, node1:e0e, node1:e0f	
Cluster			
node0_clus1	node0:e0a	local-only	Cluster
	Failover Targets:	node0:e0a, node0:e0b	
node0_clus2	node0:e0a	local-only	Cluster
	Failover Targets:	node0:e0b, node0:e0a	
node1_clus1	node1:e0a	local-only	Cluster
	Failover Targets:	node1:e0a, node1:e0b	
node1_clus2	node1:e0a	local-only	Cluster
	Failover Targets:	node1:e0b, node1:e0a	

## network interface start-cluster-check

(DEPRECATED)-Use the network interface check cluster-connectivity start command

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

This command has been deprecated and may be removed in a future version of ONTAP. Use the **network interface check cluster-connectivity start** command instead.

The **network interface start-cluster-check** command initiates an accessibility check from every logical interface to every aggregate. Automatic checks run periodically, but this command manually

initiates a check immediately.

This command produces no direct output. Any errors encountered during the check are reported in the event log. See the [event log show](#) command for more information.

## Examples

This example shows an execution of this command, with all parameters and output.

```
cluster1::> network interface start-cluster-check
```

## Related Links

- [event log show](#)

# network interface capacity show

Display the number of IP data LIFs capable of being configured on the cluster.

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **network interface capacity show** command displays the number of IP LIFs of role **data** supported on the cluster, as well as the number of IP LIFs of role **data** currently configured on the cluster.

The number of IP LIFs of role **data** that are supported on a node depends on the hardware platform and the Cluster's Data ONTAP version. If one or more nodes in the cluster cannot support additional LIFs, then none of the nodes in the cluster can support additional LIFs.

## Examples

The following displays the IP data LIF capacity.

```
cluster1::> network interface capacity show
      IP Data LIF      IP Data LIF
      Supported Limit      Count
-----
                1024                256
```

# network interface capacity details show

Display details about the IP data LIFs capable of being configured on each node.

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **network interface capacity details show** command displays the number of IP LIFs of role **data** that can be configured on each node, the number of IP data LIFs of role **data** that are supported on each node, and the number of IP data LIFs of role **data** that are configured to be homed on each node.

The number of IP LIFs of role **data** that are supported on a node depends on the hardware platform and the Cluster's Data ONTAP version. If one or more nodes in the cluster cannot support additional LIFs, then none of the nodes in the cluster can support additional LIFs.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ [-instance ] ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node Name**

Use this parameter to specify the node for which to obtain data LIF capacity.

**[-capacity-for-node <integer>] - Number of IP data LIFs that can be configured on the node**

This parameter specifies the number of IP LIFs of role **data** that can be configured on the node at the currently running Data ONTAP version. To view the version of a node, use the [cluster image show](#) command.

**[-limit-for-node <integer>] - Number of IP data LIFs that are supported on the node**

This parameter specifies the number of IP LIFs of role **data** that are supported on the node at the current effective cluster version (ECV). To view the version of a node, use the [cluster image show](#) command.

**[-count-for-node <integer>] - Number of IP data LIFs that are assigned to the node**

This parameter specifies the number of IP LIFs of role **data** currently configured to be homed on the node. To view LIFs homed on this node, use the [network interface show -home-node](#) command.

## Examples

The following displays the IP data LIF capacity.

```
cluster1::> network interface capacity details show
      Node      IP Data LIF Capacity  IP Data LIF Supported Limit  IP Data LIF Count
-----
      node1      512                    512                    128
      node2      512                    512                    128
```

# network interface check cluster-connectivity show

Display the Cluster Connectivity Log

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `network interface check cluster-connectivity show` command displays the cluster check result log.

## Parameters

`{ [-fields <fieldname>, ... ] }`

If you specify the `-fields <fieldname>, ...` parameter, the command displays only the fields that you specify.

`[ [-n ] ]`

Selects IP addresses instead of LIF names.

`[ [-instance ] ]`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-node {<nodename>|local}] - Node`

Selects cluster health records that match the specified node name.

**[-record-number <integer>] - Record Number**

Selects the cluster health records that match specified record number.

**[-date-time {MM/DD/YYYY HH:MM:SS [{+|-}hh:mm]}] - Record Date**

Selects the cluster health records that match the specified date and time.

**[-src-name <text>] - Source LIF Name**

Selects the cluster health records that match the specified source LIF name.

**[-src-addr <IP Address>] - Source IP Address**

Selects the cluster health records that match the specified source IP address.

**[-dst-name <text>] - Destination LIF Name**

Selects the cluster health records that match the specified destination LIF name.

**[-dst-addr <IP Address>] - Destination IP Address**

Selects the cluster health records that match the specified destination IP address.

**[-loss {None|Partial|All}] - Packet Loss**

Selects the cluster health records that match the specified loss value.

## Examples

The following example displays the cluster connectivity records.

```
cluster1::> network interface check cluster-connectivity show
```

Node	Date		Source LIF	Destination LIF	Packet Loss
-----					
node1					
	8/26/2020 10:35:36	-04:00	node1_clus_1	node1_clus_2	none
	8/26/2020 10:35:37	-04:00	node1_clus_1	node2_clus_1	none
	8/26/2020 10:35:38	-04:00	node1_clus_1	node2_clus_2	none
	8/26/2020 10:35:39	-04:00	node1_clus_2	node1_clus_1	none
	8/26/2020 10:35:40	-04:00	node1_clus_2	node2_clus_1	none
	8/26/2020 10:35:41	-04:00	node1_clus_2	node2_clus_2	none
node2					
	8/26/2020 10:35:36	-04:00	node2_clus_1	node2_clus_2	none
	8/26/2020 10:35:37	-04:00	node2_clus_1	node1_clus_1	none
	8/26/2020 10:35:38	-04:00	node2_clus_1	node1_clus_2	none
	8/26/2020 10:35:39	-04:00	node2_clus_2	node2_clus_1	none
	8/26/2020 10:35:40	-04:00	node2_clus_2	node1_clus_1	none
	8/26/2020 10:35:41	-04:00	node2_clus_2	node1_clus_2	none

12 entries were displayed.

# network interface check cluster-connectivity start

Start the cluster check function

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **network interface check cluster-connectivity start** command initiates an accessibility check from every logical interface to every aggregate. Automatic checks run periodically, but this command manually initiates a check immediately.

This command produces no direct output. Any errors encountered during the check are reported via the `cluster-check show` and the event log. See the [network interface check cluster-connectivity show](#) and [event log show](#) commands for more information.

## Parameters

**-node {<nodename>|local} - Node**

This optionally selects the node on which to initiate the accessibility check. If no node is specified, the accessibility check is initiated on the local node.

## Examples

This example shows an execution of this command with no parameter which will initiate the accessibility check on the local node.

```
cluster1::> network interface check cluster-connectivity start
```

## Related Links

- [event log show](#)

# network interface check failover show

Discover if any LIFs might become inaccessible during a node outage, due to over-provisioning

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command identifies logical interfaces (LIFs) at risk of becoming inaccessible if their hosting nodes were to experience an outage. The source-nodes parameter is the only required input.

The tuple <destination-nodes, vserver-name, lif-name> is sufficient to uniquely identify a record in the returned listing. All fields other than source-nodes can be filtered on in the usual fashion. There are some examples of this filtering below.

## Parameters

### { [-fields <fieldname>, ... ] }

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

### [ [-instance ] ] }

If you specify the **-instance** parameter, the command displays detailed information about all fields.

### **[-destination-nodes <nodename>, ... ] - Set Of Nodes Over Capacity**

Use this parameter to display the nodes an at-risk LIF or LIFs could fail over to.

### **[-vserver-name <vserver>] - Vserver Name**

Use this parameter to display only LIFs on the Vserver you specify.

### **[-lif-name <lif-name>] - LIF Name**

Use this parameter to display at-risk information only about the LIF or LIFs whose name you specify.

### **-source-nodes <nodename>, ... - Nodes Going Down**

List of nodes to test. At-risk LIFs currently hosted on these nodes will be identified. The list should contain no more than half the nodes in the cluster.

### **[-over-amount <integer>] - Amount Capacity Exceeded**

Use this parameter to select only at-risk LIFs associated with a set of destination nodes whose amount over capacity matches the number you specify.

Note that the number of LIFs considered to be at risk may be higher than the actual amount over capacity a given set of nodes is. Once a given set of nodes is determined to be potentially over capacity, all LIFs whose set of failover target nodes is an exact match are marked as at risk. The amount over capacity is an upper bound on the number LIFs which could become unhosted if LIFs were to fail over in a random order, each to a target randomly selected from that LIF's configured failover targets.

### **[-failover-group <failover-group>] - Failover Group Name**

Use this parameter to display information only about at-risk LIFs whose failover-group you specify.

```
[-failover-policy {system-defined|local-only|sfo-partner-only|disabled|broadcast-domain-wide}]
```

### - Failover Policy

Use this parameter to display information only about at-risk LIFs whose failover-policy you specify.

## Examples

The following example shows all the at-risk LIFs for a specific two-node outage in a six-node cluster.

```
cluster1::> network interface check failover show -source-nodes node1,node5

Destination Nodes: node2, node3, node4, node6
Amount Over Capacity: 2
Vserver          Logical Interface  Failover Group  Failover Policy
-----
vs0              data1              Default         broadcast-domain-wide
                data2              Default         broadcast-domain-wide
                data3              Default         broadcast-domain-wide
vs1              data1              Custom_Name     broadcast-domain-wide

Destination Nodes: node2
Amount Over Capacity: 1
Vserver          Logical Interface  Failover Group  Failover Policy
-----
vs0              data6              Default         sfo-partner-only
vs1              data7              Default         sfo-partner-only
```

The following example shows the same two-node outage scenario, but now with some filtering applied to the results.

```
cluster1::> network interface check failover show -source-nodes node1,node5
-destination-nodes node2,node3,node4,node6 -failover-group Def*

Destination Nodes: node2, node3, node4, node6
Amount Over Capacity: 2
Vserver          Logical Interface  Failover Group  Failover Policy
-----
vs0              data1              Default         broadcast-domain-wide
                data2              Default         broadcast-domain-wide
                data3              Default         broadcast-domain-wide
```

## network interface dns-lb-stats show

Show the DNS load-balancer stats for this node

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced*

privilege level.

## Description

The **network interface dns-lb-stats show** command displays the statistics for DNS load-balancing lookups for the zones belonging to the specified Vserver. These statistics represent the data for the Vserver on the local node. The following counts can be seen in the statistics output:

- **success-count** : Number of successful lookups.
- **authoritative-count** : Number of authoritative answers sent.
- **nonauthoritative-count** : Number of non authoritative answers sent.
- **rr-set-missing-count** : Number of times the RR set was missing.
- **domain-missing-count** : Number of times the domain was not be found.
- **failure-count** : Number of failed lookups.
- **dropped-count** : Number of lookups dropped.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[ -vserver <vserver> ] - Vserver**

Use this parameter to display DNS load-balancer statistics only for the specified Vservers.

**[ -zone <text> ] - DNS Zone**

Use this parameter to display DNS load-balancer statistics only for the specified DNS zones.

**[ -success-count <integer> ] - Successful Lookup Count**

Use this parameter to display DNS load-balancer statistics only for the specified number of successful lookups.

**[ -authoritative-count <integer> ] - Authoritative Answer Count**

Use this parameter to display DNS load-balancer statistics only for the specified number of authoritative answers sent.

**[ -nonauthoritative-count <integer> ] - Non Authoritative Answer Count**

Use this parameter to display DNS load-balancer statistics only for the specified number of non-authoritative answers sent.

**[-rr-set-missing-count <integer>] - RR Set Missing Count**

Use this parameter to display DNS load-balancer statistics only for the specified number of times the RR set was missing.

**[-domain-missing-count <integer>] - Name Missing Count**

Use this parameter to display DNS load-balancer statistics only for the specified number of times the domain was not found.

**[-failure-count <integer>] - Failed Lookup Count**

Use this parameter to display DNS load-balancer statistics only for the specified number of failed lookups.

**[-dropped-count <integer>] - Dropped Count**

Use this parameter to display DNS load-balancer statistics only for the specified number of dropped lookups.

## Examples

The following example displays stats for the zone "x.com".

```
cluster1::> network interface dns-lb-stats show -zone x.com
Vserver   DNS Zone      SUCCESS  AUTH  NOAUTH  NORR  NODOM  FAILED  DROP
-----
vs2
          x.com      5        5     0      0     0      0      0
```

# network interface failover-groups add-targets

Add failover targets to a failover group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **network interface failover-groups add-targets** command enables you to add a list of failover targets such as network ports, interface groups, or VLANs to an existing logical interface failover group.

## Parameters

**-vserver <vserver> - Vserver Name**

Use this parameter to specify the name of the Vservers from which this failover group is accessible.

**-failover-group <text> - Failover Group Name**

Use this parameter to specify the failover group that you want to extend.

**-targets [node>:<port],... - Failover Targets**

Use this parameter to specify the failover targets such as network ports, interface groups, or VLANs you wish to add to the failover group.

## Examples

This example shows the failover group "clyde" being extended to include additional failover targets.

```
cluster1::> network interface failover-group add-targets -vserver vs1 -failover-group
clyde -targets xena1:e0c, xena1:e0d-100, xena2:a0a
```

# network interface failover-groups create

Create a new failover group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **network interface failover-groups create** command creates a grouping of failover targets for logical interfaces on one or more nodes. Use this command to add a new network port or interface group to an existing failover group.

## Parameters

**-vserver <vserver> - Vserver Name**

Use this parameter to specify the name of the Vservers from which this failover group is accessible.

**-failover-group <text> - Failover Group Name**

Use this parameter to specify the name of the logical interface failover group that you want to create.

**-targets [node>:<port],... - Failover Targets**

Use this parameter to specify the list of failover targets (network ports, interface groups, or VLANs on a node) belonging to this failover group.

## Examples

The following example shows how to create a failover group named failover-group\_2 containing ports e1e and e2e on node Xena.

```
cluster1::> network interface failover-groups create -vserver vs0 -failover-group failover-group_2 -targets xena:e1e,xena:e2e
```

## network interface failover-groups delete

Delete a failover group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **network interface failover-groups delete** command deletes a logical interface failover group.

### Parameters

**-vserver <vserver> - Vserver Name**

Use this parameter to specify the name of the Vservers from which this failover group is accessible.

**-failover-group <text> - Failover Group Name**

Use this parameter to specify the name of the logical interface failover group to be deleted.

### Examples

The following example shows how to delete a failover group named failover-group\_2.

```
cluster1::> network interface failover-groups delete -vserver vs1 -failover-group failover-group_2
```

## network interface failover-groups modify

Modify a failover group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **network interface failover-groups modify** command enables you modify the list of network ports, interface groups, or VLANs belonging to an existing logical interface failover group. The specified list will overwrite the existing list of network ports, interface groups, and VLANs currently belonging to the logical interface failover group.

## Parameters

### **-vserver <vserver> - Vserver Name**

Use this parameter to specify the name of the Vserver(s) from which this failover group is accessible.

### **-failover-group <text> - Failover Group Name**

Use this parameter to specify the failover group that you want to modify.

### **[-targets [node>:<port],...] - Failover Targets**

Use this parameter to specify the network ports, interface groups, or VLANs you wish to now belong to the failover group.

## Examples

This example shows the failover group "clyde" being modified to now contain the specified network ports.

```
cluster1::> network interface failover-group modify -vserver vs1 -failover-group clyde
-targets xena1:e0c, xena1:e0d-100, xena2:a0a
```

# network interface failover-groups remove-targets

Remove failover targets from a failover group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **network interface failover-groups remove-targets** command enables you to specify a list of failover targets such as network ports, interface groups, or VLANs to be removed from an existing logical interface failover group.

## Parameters

### **-vserver <vserver> - Vserver Name**

Use this parameter to specify the name of the Vserver(s) from which this failover group is accessible.

### **-failover-group <text> - Failover Group Name**

Use this parameter to specify the failover group that you want to remove failover targets from.

**-targets [node]:<port>,...** - Failover Targets

Use this parameter to specify the failover targets such as network ports, interface groups, or VLANs you wish to remove from the failover group.

## Examples

This example shows the failover targets xena1:e0c and xena1:e0d-100 being removed from the failover group "clyde".

```
cluster1::> network interface failover-group remove-targets -vserver vs1 -failover
-group clyde -targets xena1:e0c, xena1:e0d-100, xena2:a0a
```

# network interface failover-groups rename

Rename a logical interface failover Group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **network interface failover-groups rename** command enables you to rename an existing logical interface failover group.

## Parameters

**-vserver <vserver> - Vserver Name**

Use this parameter to specify the name of the Vservers from which this failover group is accessible.

**-failover-group <text> - Failover Group Name**

Use this parameter to specify the failover group that you want to rename.

**-new-failover-group-name <text> - New name**

Use this parameter to specify the new name of the failover group.

## Examples

This example shows the failover group "clusterwide" being renamed "clyde".

```
cluster1::> network interface failover-group rename -failover -vserver vs1 -failover
-group clusterwide -new-failover-group-name clyde
```

# network interface failover-groups show

Display logical interface failover groups

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **network interface failover-groups show** command displays information about logical interface failover groups.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ [-instance ] ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-vserver <vserver>] - Vserver Name**

Use this parameter to display information only about the logical interface failover groups that have the target Vserver you specify.

**[-failover-group <text>] - Failover Group Name**

Use this parameter to display information only about the logical interface failover groups you specify.

**[-targets [node:<port>], ...] - Failover Targets**

Use this parameter to display information only about the logical interface failover groups that have the failover target (physical port, interface group, or VLAN) you specify.

**[-broadcast-domain <Broadcast Domain>] - Broadcast Domain**

Use this parameter to display information only about the logical interface failover groups that have the broadcast domain you specify.

## Examples

The following example displays information about all logical interface failover groups on a two node cluster.

```
cluster1::> network interface failover-groups show
                Failover
```

Vserver	Group	Targets
Cluster	Cluster	node1:e1a, node1:e2a, node2:e1a, node2:e2a,
cluster1	Default	node1:e0M, node1:e0a, node1:e0b, node1:e0c, node1:e0d, node2:e0M, node2:e0a, node2:e0b, node2:e0c, node2:e0d

## network interface lif-weights show

Show the load-balancer LIF weights

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

### Description

The **network interface lif-weights show** command displays the weights assigned to each LIF in a DNS load-balancing zone in a Vserver.

### Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**{ [-instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-vserver <vserver>] - Vserver**

Use this parameter to display information only for the specified Vservers.

**[-zone <text>] - DNS Zone**

Use this parameter to display information only for the specified DNS zones.

**[-address <IP Address>] - Network Address**

Use this parameter to display information only for the specified IP addresses.

**[-weight <double>] - Load Balancer Weight**

Use this parameter to display information only for the specified load balancer weights

## Examples

The following example displays LIF weights for vserver "vs1".

```
cluster1::> network interface lif-weights show -vserver vs1
```

Vserver	DNS Zone	Network Address	Weight
vs1	a.com	4.4.4.4	12.4206
	x.com	1.1.1.1	12.4206
	x.com	10.72.46.236	12.4206

3 entries were displayed.

## network interface service show

Display available interface services

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `network interface service show` command displays available services for IP LIFs and the TCP or UDP ports that each service listens on. The ports listed in this table correspond to well-known ports that each service can be expected to open a listening socket. Services that do not listen for ingress connections are presented with an empty port list.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the `-fields <fieldname>, ...` parameter, the command displays only the fields that you specify.

**[ -restrictions ]**

The `network interface service show-restrictions` command displays available services for IP LIFs and usage restrictions for each service. The restrictions determine which LIFs are permitted to use each service and what restrictions the service implies for the LIFs that do use it.

**[ -instance ] }**

If you specify the `-instance` parameter, the command displays detailed information about all fields.

**[-service <LIF Service Name>] - Service Name**

Selects services that match the specified service name.

**[-ports <integer>,...] - TCP/UDP Port Numbers**

Selects services that contain all IP ports in the specified list.

**[-protocol-ports <text>,...] - Protocol: Port Numbers**

Selects services that match the <protocol>:<port> combination.

**[-vserver-policy <svc\_vserver\_policy>] - Vserver Restrictions**

Selects services that match a specific vservers restriction.

**[-failover-policy <svc\_failover\_policy>] - Failover Restrictions**

Selects services that match a specific interface failover restriction.

## Examples

The following example displays the built-in services.

```
cluster1::> network interface service show
Service                Protocol:Port
-----
intercluster-core      tcp:11104
                       tcp:11105
management-bgp         tcp:179

2 entries were displayed.
```

# network interface service-policy add-service

Add an additional service entry to an existing service policy

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **network interface service-policy add-service** command adds an additional service to an existing service-policy. When an allowed address list is specified, the list applies to only the service being added. Existing services included in this policy are not impacted.

## Parameters

**-vserver <vserver name> - Vserver**

Use this parameter to specify the name of the Vserver of the service policy to be updated.

**-policy <text> - Policy Name**

Use this parameter to specify the name of service policy to be updated.

**-service <LIF Service Name> - Service entry to be added**

Use this parameter to specify the name of service to be added to the existing service policy.

**[-allowed-addresses <IP Address/Mask>, ...] - Allowed address ranges for the service**

Use this parameter to specify a list of subnet masks for addresses that are allowed to access this service. Use the value `0.0.0.0/0` to represent the wildcard IPv4 address and `::/0` to represent the wildcard IPv6 address.

## Examples

The following example shows the addition of a service to an existing service policy.

```
cluster1::> network interface service-policy show -vserver cluster1
Vserver  Policy                               Service: Allowed Addresses
-----
cluster1
          default-intercluster         intercluster-core: 0.0.0.0/0
                                         management-https: 0.0.0.0/0
default-management      management-core: 0.0.0.0/0
                                         management-autosupport: 0.0.0.0/0
                                         management-ssh: 0.0.0.0/0
                                         management-https: 0.0.0.0/0
default-route-announce  management-bgp: 0.0.0.0/0

3 entries were displayed.

cluster1::> network interface service-policy add-service -vserver cluster1 -policy
default-intercluster -service management-ssh

cluster1::> network interface service-policy show -vserver cluster1
Vserver  Policy                               Service: Allowed Addresses
-----
cluster1
          default-intercluster         intercluster-core: 0.0.0.0/0
                                         management-ssh: 0.0.0.0/0
                                         management-https: 0.0.0.0/0
default-management      management-core: 0.0.0.0/0
                                         management-autosupport: 0.0.0.0/0
                                         management-ssh: 0.0.0.0/0
                                         management-https: 0.0.0.0/0
default-route-announce  management-bgp: 0.0.0.0/0

3 entries were displayed.
```

# network interface service-policy clone

Clone an existing network service policy

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **network interface service-policy clone** command creates a new service policy that includes the same services and allowed addresses as an existing policy. Once the new service policy has been created, it can be modified as necessary without impacting the original policy.

## Parameters

**-vserver <vserver name> - Vserver**

Use this parameter to specify the name of the Vserver of the service policy to be cloned.

**-policy <text> - Policy Name**

Use this parameter to specify the name of the service policy to be cloned.

**-target-vserver <vserver name> - Vserver Name**

Use this parameter to specify the name of the vserver on which the new service policy should be created.

**-target-policy <text> - New Service Policy Name**

Use this parameter to specify the name of the new service policy.

## Examples

The following example shows the cloning of a service policy.

```
cluster1::> network interface service-policy show -vserver cluster1,ipSPACE1
Vserver      Policy          Service: Allowed Addresses
-----
cluster1
      custom1      intercluster-core: 0.0.0.0/0
                        management-core: 0.0.0.0/0
                        management-ssh: 0.0.0.0/0
default-intercluster      intercluster-core: 0.0.0.0/0
                        management-https: 0.0.0.0/0
default-management      management-core: 0.0.0.0/0
                        management-autosupport: 0.0.0.0/0
                        management-ssh: 0.0.0.0/0
                        management-https: 0.0.0.0/0
default-route-announce      management-bgp: 0.0.0.0/0
```

```

ipSPACE1
  default-intercluster      intercluster-core: 0.0.0.0/0
                           management-https: 0.0.0.0/0
default-management        management-core: 0.0.0.0/0
                           management-autosupport: 0.0.0.0/0
                           management-ssh: 0.0.0.0/0
                           management-https: 0.0.0.0/0
default-route-announce    management-bgp: 0.0.0.0/0

```

## network interface service-policy create

Create a new service policy

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **network interface service-policy create** command creates a new service policy with a list of included services. LIFs can reference this policy to control the list of services that they are able to transport on their network. Services can represent applications accessed by a LIF as well as applications served by this cluster.

## Parameters

### **-vserver <vserver name> - Vserver**

Use this parameter to specify the name of the Vserver on which the service policy will be created.

### **-policy <text> - Policy Name**

Use this parameter to specify the name of service policy to be created.

### **[-services <LIF Service Name>,...] - Included Services**

Use this parameter to specify a list of services that should be included in this policy.

### **[-allowed-addresses <IP Address/Mask>,...] - Allowed Addresses**

Use this parameter to specify a list of subnet masks for addresses that are allowed to access the services in this policy. Use the value **0.0.0.0/0** to represent the wildcard IPv4 address and **::/0** to represent the wildcard IPv6 address.

## Examples

The following example shows the creation of a service policy with no initial services.

```
cluster1::> network interface service-policy create -vserver cluster1 -policy empty

cluster1::> network interface service-policy show -vserver cluster1
Vserver   Policy                               Service: Allowed Addresses
-----
cluster1
          default-intercluster          intercluster-core: 0.0.0.0/0
                                         management-https: 0.0.0.0/0
default-management      management-core: 0.0.0.0/0
                                         management-autosupport: 0.0.0.0/0
                                         management-ssh: 0.0.0.0/0
                                         management-https: 0.0.0.0/0
default-route-announce  management-bgp: 0.0.0.0/0
empty                  -

4 entries were displayed.
```

The following example shows the creation of a new service policy with a specified service list.

```

cluster1::> network interface service-policy create -vserver cluster1 -policy custom
-services intercluster-core,management-ssh

cluster1::> network interface service-policy show -vserver cluster1
Vserver   Policy                               Service: Allowed Addresses
-----
cluster1
          custom                       intercluster-core: 0.0.0.0/0
                                          management-ssh: 0.0.0.0/0
default-intercluster  intercluster-core: 0.0.0.0/0
                                          management-https: 0.0.0.0/0
default-management   management-core: 0.0.0.0/0
                                          management-autosupport: 0.0.0.0/0
                                          management-ssh: 0.0.0.0/0
                                          management-https: 0.0.0.0/0
default-route-announce management-bgp: 0.0.0.0/0
empty           -

5 entries were displayed.

```

## network interface service-policy delete

Delete an existing service policy

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

The **network interface service-policy delete** command deletes an existing service policy.

### Parameters

**-vserver <vserver name> - Vserver**

Use this parameter to specify the name of the Vserver of the service policy to be deleted.

**-policy <text> - Policy Name**

Use this parameter to specify the name of the service policy to be deleted.

### Examples

The following example shows the deletion of a service policy.

```

cluster1::> network interface service-policy show -vserver cluster1
Vserver   Policy                               Service: Allowed Addresses
-----

```

```

cluster1
  custom          intercluster-core: 0.0.0.0/0
                  management-ssh: 0.0.0.0/0
                  management-https: 0.0.0.0/0
default-intercluster  intercluster-core: 0.0.0.0/0
                    management-https: 0.0.0.0/0
default-management    management-core: 0.0.0.0/0
                    management-autosupport: 0.0.0.0/0
                    management-ssh: 0.0.0.0/0
                    management-https: 0.0.0.0/0
default-route-announce management-bgp: 0.0.0.0/0

4 entries were displayed.

cluster1::> network interface service-policy delete -vserver cluster1 -policy custom

cluster1::> network interface service-policy show -vserver cluster1
Vserver  Policy          Service: Allowed Addresses

## network interface service-policy modify-service

Modify a service entry in an existing service policy

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

The `network interface service-policy modify-service` command modifies the policy-specific attributes of a service that is already included in a particular service policy. Other services in the policy are not impacted by the change.

### Parameters

**-vserver <vserver name> - Vserver**

Use this parameter to specify the name of the Vserver of the service policy to be updated.

**-policy <text> - Policy Name**

Use this parameter to specify the name of service policy to be updated.

**-service <LIF Service Name> - Service entry to be modified**

Use this parameter to specify the name of service to be updated.

**-allowed-addresses <IP Address/Mask>, ... - Allowed address ranges for the service**

Use this parameter to specify a list of subnet masks for addresses that are allowed to access this service. Use the value `0.0.0.0/0` to represent the wildcard IPv4 address and `::/0` to represent the wildcard IPv6 address.

## Examples

The following example shows the modification of a service on an existing service policy.

```
cluster1::> network interface service-policy show -vserver cluster1
Vserver  Policy                Service: Allowed Addresses
-----
cluster1
          default-intercluster  intercluster-core: 0.0.0.0/0
                                management-https: 0.0.0.0/0
default-management  management-core: 0.0.0.0/0
                                management-autosupport: 0.0.0.0/0
                                management-ssh: 0.0.0.0/0
                                management-https: 0.0.0.0/0
default-route-announce  management-bgp: 0.0.0.0/0

3 entries were displayed.

cluster1::> network interface service-policy modify-service -vserver cluster1 -policy
default-management -service management-ssh -allowed-addresses 10.1.0.0/16

cluster1::> network interface service-policy show -vserver cluster1
Vserver  Policy                Service: Allowed Addresses
-----
cluster1
          default-intercluster  intercluster-core: 0.0.0.0/0
                                management-https: 0.0.0.0/0

```

# network interface service-policy remove-service

Remove a service entry from an existing service policy

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **network interface service-policy remove-service** command removes an individual service from an existing service policy. Other services in the the policy are not impacted by the change.

## Parameters

**-vserver <vserver name> - Vserver**

Use this parameter to specify the name of the Vserver of the service policy to be updated.

**-policy <text> - Policy Name**

Use this parameter to specify the name of service policy to be updated.

**-service <LIF Service Name> - Service entry to be removed**

Use this parameter to specify the name of service to be removed from the existing service policy.

## Examples

The following example shows the removal of a service from an existing service policy.

```
cluster1::> network interface service-policy show -vserver cluster1
Vserver  Policy                               Service: Allowed Addresses
-----
cluster1
          default-intercluster         intercluster-core: 0.0.0.0/0
                                         management-https: 0.0.0.0/0
default-management      management-core: 0.0.0.0/0
                                         management-autosupport: 0.0.0.0/0
                                         management-ssh: 0.0.0.0/0
                                         management-https: 0.0.0.0/0
default-route-announce  management-bgp: 0.0.0.0/0

3 entries were displayed.

cluster1::> network interface service-policy remove-service -vserver cluster1 -policy
default-management -service management-autosupport

cluster1::> network interface service-policy show -vserver cluster1
Vserver  Policy                               Service: Allowed Addresses
```

```

-----
cluster1
      default-intercluster      intercluster-core: 0.0.0.0/0
                                management-https: 0.0.0.0/0
default-management      management-core: 0.0.0.0/0
                                management-ssh: 0.0.0.0/0
                                management-https: 0.0.0.0/0
default-route-announce  management-bgp: 0.0.0.0/0

3 entries were displayed.

```

## network interface service-policy rename

Rename an existing network service policy

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

The **network interface service-policy rename** command assigns a new name to an existing service policy without disrupting the LIFs using the policy.

### Parameters

**-vserver <vserver name> - Vserver**

Use this parameter to specify the name of the Vserver of the service policy to be renamed.

**-policy <text> - Policy Name**

Use this parameter to specify the name of the service policy to be renamed.

**-new-name <text> - New Service Policy Name**

Use this parameter to specify the new name for the service policy.

### Examples

The following example shows the renaming of a service policy.

```

cluster1::> network interface service-policy show -vserver cluster1
Vserver  Policy                Service: Allowed Addresses
-----
cluster1
      custom            intercluster-core: 0.0.0.0/0
                                management-autosupport: 0.0.0.0/0
                                management-ssh: 0.0.0.0/0
                                management-https: 0.0.0.0/0
default-intercluster  intercluster-core: 0.0.0.0/0

```

```

management-https: 0.0.0.0/0
default-management    management-core: 0.0.0.0/0
                    management-autosupport: 0.0.0.0/0
                    management-ssh: 0.0.0.0/0
                    management-https: 0.0.0.0/0
default-route-announce management-bgp: 0.0.0.0/0

```

4 entries were displayed.

```
cluster1::> network interface service-policy rename -vserver cluster1 -policy custom
-new-name system
```

```
cluster1::> network interface service-policy show -vserver cluster1
```

```
Vserver  Policy                               Service: Allowed Addresses
```

```
-----
```

cluster1

```

      system                                intercluster-core: 0.0.0.0/0
                                           management-autosupport: 0.0.0.0/0
                                           management-ssh: 0.0.0.0/0
                                           management-https: 0.0.0.0/0
default-intercluster  intercluster-core: 0.0.0.0/0
                                           management-https: 0.0.0.0/0
default-management    management-core: 0.0.0.0/0
                                           management-autosupport: 0.0.0.0/0
                                           management-ssh: 0.0.0.0/0
                                           management-https: 0.0.0.0/0
default-route-announce management-bgp: 0.0.0.0/0

```

4 entries were displayed.

## network interface service-policy restore-defaults

Restore default settings to a service policy

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

The `network interface service-policy restore-defaults` command restores a built-in service-policy to its original state. The default list of services replaces any customizations that have been applied by an administrator. All included services will be updated to use the default allowed address list.

### Parameters

**-vserver <vserver name> - Vserver**

Use this parameter to specify the name of the Vserver of the service policy to be restored.

**-policy <text> - Policy Name**

Use this parameter to specify the name of the service policy to be restored.

## Examples

The following example shows the restoration of a service policy's default settings.

```
cluster1::> network interface service-policy show -vserver cluster1
Vserver  Policy                               Service: Allowed Addresses
-----
cluster1
          default-intercluster         intercluster-core: 10.1.0.0/16
                                         management-ssh: 10.1.0.0/16
                                         management-https: 10.1.0.0/16
default-management      management-core: 0.0.0.0/0
                                         management-autosupport: 0.0.0.0/0
                                         management-ssh: 0.0.0.0/0
                                         management-https: 0.0.0.0/0
default-route-announce management-bgp: 0.0.0.0/0

3 entries were displayed.

cluster1::> network interface service-policy restore-defaults -vserver cluster1
-policy default-intercluster

cluster1::> network interface service-policy show -vserver cluster1
Vserver  Policy                               Service: Allowed Addresses
-----
cluster1
          default-intercluster         intercluster-core: 0.0.0.0/0
                                         management-https: 0.0.0.0/0
default-management      management-core: 0.0.0.0/0
                                         management-autosupport: 0.0.0.0/0
                                         management-ssh: 0.0.0.0/0
                                         management-https: 0.0.0.0/0
default-route-announce management-bgp: 0.0.0.0/0

3 entries were displayed.
```

## network interface service-policy show

Display existing service policies

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege

level.

## Description

The `network interface service-policy show` command displays existing service policies.

## Parameters

`{ [-fields <fieldname>, ... ] }`

If you specify the `-fields <fieldname>, ...` parameter, the command displays only the fields that you specify.

`[ -instance ] }`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-vserver <vserver name>] - Vserver`

Selects service policies that match the specified vserver name.

`[-policy <text>] - Policy Name`

Selects service policies that match the specified service policy name.

`[-services <LIF Service Name>, ...] - Included Services`

Selects service policies that contain all services in the specified list of service names.

`[-service-allowed-addresses <text>, ...] - Service: Allowed Addresses`

Selects service policies that contain all "`<service>:<allowed-addresses>`" in the specified list of addresses.

## Examples

The following example displays the built-in service policies.

```
cluster1::> network interface service-policy show -vserver cluster1
Vserver   Policy                               Service: Allowed Addresses
-----
cluster1
  default-intercluster                intercluster-core: 0.0.0.0/0
                                       management-https: 0.0.0.0/0
default-management                    management-core: 0.0.0.0/0
                                       management-autosupport: 0.0.0.0/0
                                       management-ssh: 0.0.0.0/0
                                       management-https: 0.0.0.0/0
default-route-announce                management-bgp: 0.0.0.0/0

3 entries were displayed.
```

# network ipspace create

Create a new IPspace

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

IPspaces are distinct IP address spaces in which Storage Virtual Machines (SVMs) reside. The "Cluster" IPspace and "Default" IPspace are created by default. You can create more custom IPspaces when you need your SVMs to have overlapping IP addresses, or you need more control over networking configurations for cluster peering. Please reference the "Network Management Guide" for the limit of how many custom IPspaces are supported on your system..

## Parameters

**-ipSPACE <IPspace> - IPspace name**

The name of the IPspace to be created.

- The name must contain only the following characters: A-Z, a-z, 0-9, ".", "-", or "\_".
- The first character of each label, delimited by ".", must be one of the following characters: A-Z or a-z.
- The last character of each label, delimited by ".", must be one of the following characters: A-Z, a-z or 0-9.
- The maximum supported length is 47 characters.
- The system reserves the following names: "all", "local" and "localhost".
- The system provides the following IPspaces: "Cluster" and "Default".

## Examples

The following example creates IPspace "ips1".

```
cluster1::> network ipspace create -name ips1
```

# network ipspace delete

Delete an IPspace

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Delete an IPspace that contains no ports or Vservers.

## Parameters

### **-ipSPACE <IPspace> - IPspace name**

The name of the IPspace to be deleted. If the IPspace is associated with one or more logical-interfaces, you must delete them before you can delete the IPspace.

## Examples

The following example deletes the IPspace "ips1".

```
cluster1::> network ipspace delete -ipSPACE ips1
```

# network ipspace rename

Rename an IPspace

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Rename an IPspace.

## Parameters

### **-ipSPACE <IPspace> - IPspace name**

The name of the IPspace to be renamed.

### **-new-name <IPspace> - New Name**

The new name for the IPspace.

- The name must contain only the following characters: A-Z, a-z, 0-9, ".", "-", or "\_".
- The first character of each label, delimited by ".", must be one of the following characters: A-Z or a-z.
- The last character of each label, delimited by ".", must be one of the following characters: A-Z, a-z or 0-9.
- The maximum supported length is 47 characters.
- The system reserves the following names: "all", "cluster", "local" and "localhost".

## Examples

The following example renames IPspace "ips1" to "ips2".

```
cluster1::> network ipspace rename -ipspace ips1 -new-name ips2
```

## network ipspace show

Display IPspace information

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Display network IPspaces.

## Parameters

{ [-fields <fieldname>, ...]

Specify the fields to be displayed for each IPspace.

| [-instance ] }

Display all parameters of the IPspace objects.

[-ipspace <IPspace>] - IPspace name

Display the names of the IPspaces.

[-ports [node>:<port], ...] - Ports

The list of network ports assigned to each IPspace.

[-broadcast-domains <Broadcast Domain>, ...] - Broadcast Domains

The list of broadcast domains that belong to the IPspace.

[-vservers <vserver name>, ...] - Vservers

The list of Vservers assigned to each IPspace.

## Examples

The following example displays general information about IPspaces.

```
cluster1::> network ipspace show
IPspace          Vserver List          Broadcast Domains
-----
Cluster
```

	Cluster	
Default		-
	cluster1, vs1, vs2	br1, br2, br3

2 entries were displayed.

## network ndp default-router delete-all

Delete default routers on a given IPspace

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

The **network ndp default-router delete-all** command deletes default router lists from the specified IPspace.

### Parameters

**-ipspace <IPspace>** - IPspace Name

Use this parameter to specify the IPspace where the default routers are to be deleted.

### Examples

The following example deletes default routers from IPspace ips1.

```
cluster1::*> network ndp default-router delete-all -ipspace ips1
```

## network ndp default-router show

Display default routers

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

The **network ndp default-router show** command displays Neighbor Discovery Protocol (NDP) default routers learned on a specified port.

### Parameters

{ [-fields <fieldname>, ...]

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[`-instance` ] }**

If you specify the `-instance` parameter, the command displays detailed information about all fields.

**[`-node` {<nodename>|local}] - Node**

Displays the NDP default routers from the specified node.

**[`-ipSpace` <IPspace>] - IPspace name**

Displays the NDP default routers from the specified IPspace.

**[`-port` {<netport>|<ifgrp>}] - Port**

Displays the NDP default routers from the specified port.

**[`-router-addr` <IP Address>] - Router Address**

Displays the default routers that have the specified IPv6 addresses.

**[`-flag` {none|managed-address-DHCPv6|other-DHCPv6}] - Flag**

Displays the default routers that have the specified flag. The flag indicates whether addresses are available via DHCPv6 or other configuration information is available via DHCPv6.

**[`-expire-time` {[<integer>d][<integer>h][<integer>m][<integer>s]|never|expired}] - Expire Time**

Displays the default routers that have the specified expire time.

## Examples

The following example displays NDP default routers on local port e0f.

```
cluster1::*> network ndp default-router show -port e0f -node local

Node: node1
IPspace: Default
Port      Router Address          Flag      Expire Time
-----
e0f      fe80::5:73ff:fea0:107   none      0d0h23m9s
```

## network ndp neighbor create

Create a static NDP neighbor entry

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

The `network ndp neighbor create` command creates a static Neighbor Discovery Protocol (NDP)

neighbor entry within a Vserver.

## Parameters

### **-vserver <vserver name> - Vserver Name**

Use this parameter to specify the Vserver on which the NDP neighbor is to be created.

### **-neighbor <IP Address> - Neighbor Address**

Use this parameter to specify the neighbor's IPv6 address.

### **-mac-address <MAC Address> - MAC Address**

Use this parameter to specify the neighbor's MAC address.

## Examples

The following example creates a NDP neighbor entry within Vserver vs0.

```
cluster1::*> network ndp neighbor create -vserver vs0 -neighbor 20:20::20 -mac-address 10:10:10:0:0:1
```

## network ndp neighbor delete

Delete a static NDP neighbor entry

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

The **network ndp neighbor delete** command deletes a static Neighbor Discovery Protocol (NDP) neighbor from a Vserver.

## Parameters

### **-vserver <vserver name> - Vserver Name**

Use this parameter to specify the Vserver on which the NDP neighbor is to be deleted.

### **-neighbor <IP Address> - Neighbor Address**

Use this parameter to specify the neighbor's IPv6 address.

## Examples

The following example deletes a NDP neighbor entry within Vserver vs0.

```
cluster1::*> network ndp neighbor delete -vserver vs0 -neighbor 20:20::20
```

## network ndp neighbor show

Display static NDP neighbor entries

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

### Description

The `network ndp neighbor show` command displays a group of static Neighbor Discovery Protocol (NDP) neighbors within one or more Vservers. You can view static NDP neighbors within specified Vservers, neighbors with specified IPv6 address, and neighbors with specified MAC address.

### Parameters

{ [-fields <fieldname>, ... ] }

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

[ -instance ] }

If you specify the `-instance` parameter, the command displays detailed information about all fields.

[ -vserver <vserver name> ] - **Vserver Name**

Displays the static NDP neighbors that have the specified Vserver as their origin.

[ -neighbor <IP Address> ] - **Neighbor Address**

Displays the static NDP neighbors that have the specified IPv6 address.

[ -mac-address <MAC Address> ] - **MAC Address**

Displays the static NDP neighbors that have the specified MAC address.

### Examples

The following example displays all of the static NDP neighbors configured on Vserver vs0.

```
cluster1::*> network ndp neighbor show -vserver vs0
Vserver      Neighbor      MAC Address
-----
vs0
              10:10::10     04:04:04:04:04:04
              20:20::20     01:01:01:01:01:01
```

2 entries were displayed.

# network ndp neighbor active-entry delete

Delete active neighbor entry from a System or Admin Vserver

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **network ndp neighbor active-entry delete** command deletes a Network Discovery Protocol (NDP) neighbor entry on the specified port from a given Vserver's subnet group.

## Parameters

**-node {<nodename>|local} - Node**

Use this parameter to specify the node on which the neighbor entry is to be deleted.

**-vserver <vserver> - System or Admin Vserver Name**

Use this parameter to specify the System or Admin Vserver on which the neighbor entry is to be deleted.

**-subnet-group <IP Address/Mask> - Subnet Group**

Use this parameter to specify the subnet group from which the neighbor entry is to be deleted.

**-neighbor <IP Address> - Neighbor**

Use this parameter to specify the IPv6 address of the neighbor entry which is to be deleted.

**-port {<netport>|<ifgrp>} - Port**

Use this parameter to specify the port on which the neighbor entry is to be deleted.

## Examples

The following example deletes a neighbor entry from the Admin Vserver cluster1:

```
cluster1::*> network ndp neighbor active-entry delete -vserver cluster1 -node local  
-subnet-group ::/0 -neighbor fe80:4::5:73ff:fea0:107 -port e0d
```

# network ndp neighbor active-entry show

Display active neighbor entries organized by Vserver

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **network ndp neighbor active-entry show** command displays Network Discovery Protocol (NDP) neighbor cache entries on one or more nodes. You can view ndp neighbors within specified nodes and within specified System or Admin Vservers.

## Parameters

**{ [-fields <fieldname>,...]**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[-verbose ]**

Displays the expire time, state, is-router, and probe count fields.

**[-instance ]}**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node**

Displays the NDP neighbors from the specified node.

**[-vserver <vserver>] - System or Admin Vserver Name**

Displays the NDP neighbors from the specified System or Admin Vserver. Data and Node Vservers do not have dynamic NDP neighbors.

**[-subnet-group <IP Address/Mask>] - Subnet Group**

Displays the NDP neighbors in the specified subnet group.

**[-neighbor <IP Address>] - Neighbor**

Displays the NDP neighbors that have the specified IPv6 address.

**[-port {<netport>|<ifgrp>}] - Port**

Displays the NDP neighbors on the specified port.

**[-mac-address <MAC Address>] - MAC Address**

Displays the NDP neighbors have the specified MAC address.

**[-expire-time {[<integer>d][<integer>h][<integer>m][<integer>s]|never|expired}] - Expire Time**

Displays the NDP neighbors have the specified expire time.

**[-state {<nostate|incomplete|reachable|stale|delay|probe|unknown>}] - State**

Displays the NDP neighbors in the specified state.

**[-is-router {true|false}] - Is Router**

Displays the NDP neighbor which is a router.

**[-probe-count <integer>] - Probe Count**

Displays the NDP neighbors with the specified probe count. Probe count is the number of times that this neighbor's MAC address has been queried.

**[-is-static {true|false}] - Is Static**

Displays the NDP neighbors which are statically configured.

## Examples

The following example displays NDP neighbors on the Admin Vserver cluster1:

```
cluster1::*> network ndp neighbor active-entry show -vserver cluster1

Node: node1
Vserver: cluster1
Subnet Group: ::/0
Neighbor                MAC Address          Port
-----
fe80:4::5:73ff:fea0:107  00:05:73:a0:01:07    e0d
fe80:4::226:98ff:fe0c:b6c1  00:26:98:0c:b6:c1    e0d
fe80:4::4255:39ff:fe25:27c1  40:55:39:25:27:c1    e0d
3 entries were displayed.
```

## network ndp prefix delete-all

Delete IPv6 prefixes on a given IPspace

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

The **network ndp prefix delete-all** command deletes all prefixes learned from the specified IPspace.

### Parameters

**-ipSPACE <IPspace> - IPspace Name**

Use this parameter to specify the IPspace where the IPv6 prefixes are to be deleted.

## Examples

The following example deletes all IPv6 prefixes within IPspace ips1.

```
cluster1::*> network ndp prefix delete-all -ipSPACE ips1
```

# network ndp prefix show

Display IPv6 prefixes

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **network ndp prefix show** command displays IPv6 prefixes on one or more nodes.

## Parameters

**{ [-fields <fieldname>, ... ]**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[ -verbose ]**

Displays the valid-lifetime, preferred-lifetime, origin and advertising-router fields.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node**

Displays the IPv6 prefixes from the specified node.

**[-ipspace <IPspace>] - IPspace name**

Displays the IPv6 prefixes from the specified IPspace.

**[-port {<netport>|<ifgrp>}] - Port**

Displays the IPv6 prefixes on the specified port.

**[-prefix <IP Address/Mask>] - Prefix**

Displays the IPv6 prefixes with the specified prefix value.

**[-flag {none|on-link|autonomous|on-link-autonomous}] - Flag**

Displays the IPv6 prefixes with the specified flag. The flag indicates whether a prefix is on-link and whether it can be used in autonomous address configuration.

**[-valid-lifetime {<unsigned integer>|infinity}] - Valid Lifetime**

Displays the IPv6 prefixes having the specified valid lifetime in seconds.

**[-preferred-lifetime {<unsigned integer>|infinity}] - Preferred Lifetime**

Displays the IPv6 prefixes having the specified preferred lifetime in seconds.

**[-expire-time {[<integer>d][<integer>h][<integer>m][<integer>s]|never|expired]} - Expire Time**

Displays the IPv6 prefixes having the specified expire time.

**[-origin {router-advertise|renumber-request|static|kernel|unknown}] - Origin of the Prefix**

Displays the IPv6 prefixes with the specified origin.

**[-advertising-router <IP Address>,...] - Router that Advertised the Prefix**

Displays the IPv6 prefixes which are propagated by the specified router list.

## Examples

The following example displays IPv6 prefixes on port e0f.

```
cluster1::*> network ndp prefix show -port e0f -node local

Node: node1
IPspace: Default
Port      Prefix                Flag                Expire Time
-----
e0f      fd20:8b1e:b255:814e::/64  on-link-autonomous  29d23h56m48s
```

# network options cluster-health-notifications modify

cluster health notification options

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command enables or disables cluster health notifications on the specified node.

## Parameters

**-node {<nodename>|local} - Node**

This parameter specifies the node for which the cluster health notification status will be modified.

**[-enabled {true|false}] - Cluster Health Notifications Enabled**

Setting this parameter to **true** enables cluster health notification. Setting it to **false** disables cluster health notification.

## Examples

The following example modifies the cluster health notification status for a node:

```
cluster1::> network options cluster-health-notifications modify -node node1 -enabled true
```

# network options cluster-health-notifications show

Display cluster health notification options

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `network options cluster-health-notifications show` command displays whether the node's cluster health notifications are enabled.

## Parameters

`{ [-fields <fieldname>, ... ] }`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

`[ [-instance ] ] }`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-node {<nodename>|local}] - Node`

This parameter specifies the node for which the cluster health notification status will be displayed.

`[-enabled {true|false}] - Cluster Health Notifications Enabled`

Selects the entries that match this parameter value.

## Examples

The following example displays the cluster health notification status for a node:

```
cluster1::> network options cluster-health-notifications show -node node1
Node: node1
Cluster Health Notifications Enabled: true
```

# network options detect-switchless-cluster modify

Modify the status of switchless cluster detection

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command enables or disables the automatic detection of a switchless cluster. A switchless cluster consists of two nodes where the cluster ports are directly connected without a switch between them.

## Parameters

**[-enabled {true|false}] - Enable Switchless Cluster Detection**

This parameter specifies whether switchless cluster detection is enabled or not. Setting this parameter to **true** enables switchless cluster detection.

## Examples

The following example enables switchless cluster detection:

```
cluster1::*> network options detect-switchless-cluster modify -enabled true
```

# network options detect-switchless-cluster show

Display the status of switchless cluster detection

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The network options detect-switchless-cluster show command displays whether switchless cluster detection is enabled.

## Examples

The following example displays whether switchless cluster detection is enabled:

```
cluster1::*> network options detect-switchless-cluster show
```

```
Enable Detect Switchless Cluster: true
```

## network options ipv6 modify

Modify IPv6 options

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

This command sets the state of IPv6 options for the cluster.

### Parameters

#### **[-enabled <true>] - IPv6 Enabled**

Setting this parameter to **true** enables IPv6 for the cluster. IPv6 cannot be disabled once it is enabled for the cluster. Call Fujitsu support personnel for guidance regarding disabling IPv6.

#### **[-is-ra-processing-enabled {true|false}] - Router Advertisement (RA) Processing Enabled**

Setting this parameter to **true** enables cluster to process IPv6 router advertisements. Setting it to **false** disables router advertisement processing by the cluster.

### Examples

The following example enables IPv6 for the cluster:

```
cluster1::> network options ipv6 modify -enabled true
```

The following example enables IPv6 Router Advertisement processing for the cluster:

```
cluster1::> network options ipv6 modify -is-ra-processing-enabled true
```

The following example disables IPv6 Router Advertisement processing for the cluster:

```
cluster1::> network options ipv6 modify -is-ra-processing-enabled false
```

## network options ipv6 show

Display IPv6 options

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command displays the current state of IPv6 options for the cluster.

## Examples

```
cluster1::> network options ipv6 show

IPv6 Enabled: false
Router Advertisement (RA) Processing Enabled: false
```

## network options load-balancing modify

Modify load balancing algorithm

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command sets the state of geometric mean algorithm for load balancing

## Parameters

**[-enable {true|false}] - Geometric Mean Algorithm for load balancing**

Setting this parameter to **true** enables the geometric mean algorithm for load balancing. Setting it to **false** disables the geometric mean algorithm for the cluster.

## Examples

```
The following example will enable the geometric mean algorithm for load
balancing.
cluster1::> network options load-balancing modify -enable true
The following example will disable the geometric mean algorithm for load
balancing.
cluster1::> network options load-balancing modify -enable false
```

## network options load-balancing show

Display load balancing algorithm

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command displays the use of geometric mean load balancing algorithm.

## Examples

```
cluster1::> network options load-balancing show
Geometric Mean Algorithm for load balancing: false
```

# network options multipath-routing modify

Modify multipath-routing

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **network options multipath-routing modify** command is used to modify cluster-wide multipath routing configuration.

## Parameters

**[-is-enabled {true|false}] - Is Multipath Routing Enabled**

This parameter specifies whether multipath routing configuration is enabled or not. Setting this parameter to **\_ true\_** enables multipath routing for all nodes in the cluster.

## Examples

```
cluster1::> network options multipath-routing modify -is-enabled true
```

# network options multipath-routing show

Display multipath-routing

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **network options multipath-routing show** command displays the multipath routing configuration for the cluster.

## Examples

```
cluster1::> network options multipath-routing show
Is Multipath Routing Enabled: false
```

# network options port-health-monitor disable-monitors

Disable one or more port health monitors

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command disables the given port health monitors for the given IPspaces in the cluster.

## Parameters

**-ipSPACE <IPspace> - IPspace Name**

The name of the IPspace for which the specified port health monitors are disabled.

**-health-monitors {l2-reachability|link-flapping|crc-errors|vswitch-link} - List of Port Health Monitors to Disable**

The port health monitors to disable.

## Examples

The following example disables the "l2\_reachability" health monitor for the "Default" IPspace.

The status of the "link\_flapping" monitor is unaffected by the command.

```
cluster1::*> network options port-health-monitor show
```

IPspace	Enabled Port Health Monitors
Cluster	l2_reachability, link_flapping
Default	l2_reachability, link_flapping

2 entries were displayed.

```
cluster1::*> network options port-health-monitor disableMonitors -ipSPACE Default
-health-monitors l2_reachability
```

```
cluster1::*> network options port-health-monitor show
```

```
IPspace          Enabled Port Health Monitors
-----          -
Cluster          l2_reachability,
                  link_flapping
Default          link_flapping
2 entries were displayed.
```

## network options port-health-monitor enable-monitors

Enable one or more port health monitors

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

This command enables the given port health monitors for the given IPspaces in the cluster.

### Parameters

**-ipSPACE <IPspace> - IPspace Name**

The name of the IPspace for which the specified port health monitors are enabled.

**-health-monitors {l2-reachability|link-flapping|crc-errors|vswitch-link} - List of Port Health Monitors to Enable**

The port health monitors to enable. Upon enabling the **l2\_reachability** health monitor, it runs in an "unpromoted" state. While in this state, the monitor does not mark any ports as unhealthy due to the l2\_reachability health check. The monitor is promoted in the "Cluster" IPspace when the "Cluster" broadcast domain is found to have passed the **l2\_reachability** health check. An EMS event called "vifmgr.hm.promoted" event is generated when the health monitor is promoted for the IPspace.

### Examples

The following example enables the "l2\_reachability" health monitor for the "Default" IPspace:

The status of the "link\_flapping" monitor is unaffected by the command.

```
cluster1::*> network options port-health-monitor show
```

```
IPspace          Enabled Port Health Monitors
-----          -
Cluster          l2_reachability,
```

```

link_flapping
Default      link_flapping
2 entries were displayed.

cluster1::*> network options port-health-monitor enableMonitors -ipSpace Default
-health-monitors l2_reachability

cluster1::*> network options port-health-monitor show

IPspace      Enabled Port Health Monitors
-----
Cluster      l2_reachability,
              link_flapping
Default      l2_reachability,
              link_flapping
2 entries were displayed.

```

## network options port-health-monitor modify

Modify port health monitors configuration

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

This command modifies the enabled port health monitors for the given IPspaces in the cluster.

### Parameters

**-ipSpace <IPspace> - IPspace Name**

The name of the IPspace for which enabled port health monitors are modified.

**[-health-monitors {l2-reachability|link-flapping|crc-errors|vswitch-link}] - List of Enabled Port Health Monitors**

All of the port health monitors that you want to enable. This command enables any port health monitors in this list that are currently disabled, and it disables any currently enabled monitors that are not in this list. Upon enabling the **l2\_reachability** health monitor, it runs in an "unpromoted" state. While in this state, the monitor does not mark any ports as unhealthy due to the l2\_reachability health check. The monitor is promoted in the "Cluster" IPspace when the "Cluster" broadcast domain is found to have passed the **l2\_reachability** health check. An EMS event called "vifmgr.hm.promoted" event is generated when the health monitor is promoted for the IPspace.

### Examples

The following example modifies the port health monitor configuration of the "Default" IPspace such that only the "link\_flapping" port health monitor is enabled. enabled for all IPspaces in the cluster.

Only the specified monitor is enabled after the modify command is issued.

```
cluster1::*> network options port-health-monitor show

IPspace          Enabled Port Health Monitors
-----          -
Cluster          l2_reachability,
                  link_flapping
Default          l2_reachability,
                  link_flapping
2 entries were displayed.

cluster1::*> network options port-health-monitor modify -ipspace Default -health
-monitors link_flapping

cluster1::*> network options port-health-monitor show

IPspace          Enabled Port Health Monitors
-----          -
Cluster          l2_reachability,
                  link_flapping
Default          link_flapping
2 entries were displayed.
```

## network options port-health-monitor show

Display port health monitors configuration

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

This command displays the enabled port health monitors for the IPspaces in the cluster.

### Parameters

**{ [-fields <fieldname>, ...]**

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**l [-instance ]}**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-ipspace <IPspace>] - IPspace Name**

Displays the port health monitors that are enabled only for the given IPspace name.

## [-health-monitors {l2-reachability|link-flapping|crc-errors|vswitch-link}] - List of Enabled Port Health Monitors

Displays the IPspaces that have the given monitors enabled.

## Examples

The following example lists all port health monitors that are enabled for all IPspaces in the cluster.

```
cluster1::*> network options port-health-monitor show
```

IPspace	Enabled Port Health Monitors
Cluster	l2_reachability, link_flapping
Default	l2_reachability, link_flapping

2 entries were displayed.

## network options send-soa modify

Modify Send SOA settings

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command sets the status of sending statement of authority record in the DNS response.

## Parameters

[-enable {true|false}] - Enable sending SOA

Setting this parameter to **true** enables sending the statement of authority (SOA) record in the DNS response. Setting it to **false** disables sending the statement of authority (SOA) record in the DNS response for the cluster.

## Examples

The following example will enable the sending of statement of authority (SOA) in the DNS response.

```
cluster1::> network options send-soa modify -enable true
```

The following example will disable the sending of statement of authority (SOA) in the DNS response.

```
cluster1::> network options send-soa modify -enable false
```

# network options send-soa show

Display Send SOA settings

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command displays whether sending the statement of authority record (SOA) in the DNS response is enabled or not.

## Examples

```
cluster1::> network options send-soa show
Enable sending SOA: true
```

# network options switchless-cluster modify

Modify switchless cluster network options

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command sets whether the cluster network is in switchless or switched mode. A switchless cluster is physically formed by connecting two nodes back-to-back, without a switch between them.

## Parameters

**[-enabled {true|false}] - Enable Switchless Cluster**

This parameter specifies whether the switchless cluster is enabled or not. Setting this parameter to **true** enables the switchless cluster.

## Examples

```
The following example enables the switchless cluster:
cluster1::*> network options switchless-cluster modify -enabled true
```

# network options switchless-cluster show

Display switchless cluster network options

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The network options `switchless-cluster show` command displays the attributes of a switchless cluster.

## Examples

```
The following example displays the attributes of the switchless cluster:  
cluster1::*> network options switchless-cluster show  
Enable Switchless Cluster: true
```

## network port delete

Delete a network port

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `network port delete` command deletes a network port that is no longer physically present on the storage system.

## Parameters

**-node {<nodename>|local} - Node**

This specifies the node on which the port is located.

**-port {<netport>|<ifgrp>} - Port**

This specifies the port to delete.

## Examples

The following example deletes port `e0c` from a node named `node0`. The command works only when the port does not physically exist on the storage system.

```
cluster1::*> network port delete -node node0 -port e0c
```

## network port modify

Modify network port attributes

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **network port modify** command enables you to change the maximum transmission unit (MTU) setting, autonegotiation setting, administrative duplex mode, and administrative speed of a specified network port.

The MTU of ports that belong to broadcast-domains must be updated through the **broadcast-domain modify** command.

Modification of a port's IPspace will only work before a node is added to a cluster, when the node is offline.

## Parameters

### **-node {<nodename>|local} - Node**

Use this parameter to specify the node on which the port is located.

### **-port {<netport>|<ifgrp>} - Port**

Use this parameter to specify the port that you want to modify.

### **[-mtu <integer>] - MTU**

The port's MTU setting. The default setting for ports in the "Cluster" IPspace is 9000 bytes. All other ports use a default value of 1500 bytes.

### **[-autonegotiate-admin {true|false}] - Auto-Negotiation Administrative**

Whether the port uses Ethernet autonegotiation to determine the highest speed and duplex mode that the port and its endpoint can support. The default setting when you create a port is **true**.

### **[-duplex-admin {auto|half|full}] - Duplex Mode Administrative**

The administrative setting for the port's duplex mode. This is the duplex mode that you prefer the port to use. Depending on network limitations, the operational value can be different from the administrative setting. The default setting when you create a port is **full**.

### **[-speed-admin {auto|10|100|1000|10000|100000|40000|25000}] - Speed Administrative**

The administrative speed setting, in megabits per second. This is the speed setting that you prefer the port to use. Depending on network limitations, the operational value can be lower than the administrative setting.

### **[-flowcontrol-admin {none|receive|send|full}] - Flow Control Administrative**

The administrative flow control setting of the port. This is the flow control setting that you prefer the port to use. Depending on network and port limitations, the operational value can be different from the administrative setting.

**[-up-admin {true|false}] - Up Administrative**

The administrative state of the port. If set to **true** , the port is used if it is operational. If set to **false** , the port is configured down.

**[-ipSPACE <IPspace>] - IPspace Name**

Use this parameter to specify the IPspace the network port is assigned to. Modification of a port's IPspace will only work before a node is added to a cluster, when the node is offline.

If there is an inconsistency between the broadcast-domain and IPspace, this parameter can be set to bring the IPspace into alignment with the broadcast-domain.

**[-ignore-health-status {true|false}] - Ignore Port Health Status**

Use this parameter to specify that the system ignore network port health status of the specified port for the purpose of hosting a logical interface.

## Examples

The following example modifies port e0a on a node named node0 not to use auto-negotiation, to preferably use half duplex mode, and to preferably run at 100 Mbps.

```
cluster1::> network port modify -node node0 -port e0a -autonegotiate-admin false
-duplex-admin half -speed-admin 100
```

# network port show-address-filter-info

Print the port's address filter information

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **network port show-address-filter-info** command displays information about the port's address filter.

## Parameters

{ [-fields <fieldname>, ... ] }

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

{ [-instance ] }

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**-node <nodename> - Node**

Use this parameter to specify the node.

**-port {<netport>|<ifgrp>} - Port**

Use this parameter to specify the port. For example, e0c.

**[-num-total <integer>] - Total Number Of Entries**

Use this parameter to specify the total number of entries.

**[-num-used <integer>] - Number Of Used Entries**

Use this parameter to specify the number of used entries.

**[-used-entries <text>,...] - The Used Entries**

Use this parameter to list the used entries.

## Examples

The following example displays information of the given port's address filter on the specified node of the cluster.

```
cluster1::*> network port show-address-filter-info -node local -port e0c
```

```
Node: node1
```

Port Name	Total Number of Address Filter Entries	Number of Used Address Filter Entries	Used Address Filter Entries
e0c	1328	3	U 0 a0 98 40 e 6 M 1 80 c2 0 0 e M 1 0 5e 0 0 fb

## network port show

Display network port attributes

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **network port show** command displays information about network ports. The command output indicates any inactive links, and lists the reason for the inactive status.

Some parameters can have "administrative" and "operational" values. The administrative setting is the preferred value for that parameter, which is set when the port is created or modified. The operational value is the actual current value of that parameter. Administrative and operational

settings are not shown for virtual ports, '-' will be displayed. Please see the physical port hosting the target virtual port for these values.

If the operational duplex mode and speed of a port cannot be determined (for instance, if the link is down), that port's status is listed as **undef**, meaning undefined. This is different from '-', meaning no value.

## Parameters

### { [-fields <fieldname>, ... ] }

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

### [ [-health ] ]

Use this parameter to display detailed health information for the specified network ports.

### [ [-instance ] ] }

If you specify the **-instance** parameter, the command displays detailed information about all fields.

### [ -node {<nodename>|local} ] - Node

Selects the network ports that match this parameter value. Use this parameter with the **-port** parameter to select a port.

### [ -port {<netport>|<ifgrp>} ] - Port

Selects the network ports that match this parameter value. If you do not use this parameter, the command displays information about all network ports.

### [ -link {off|up|down} ] - Link

Selects the network ports that match this parameter value.

### [ -mtu <integer> ] - MTU

Selects the network ports that match this parameter value.

### [ -autonegotiate-admin {true|false} ] - Auto-Negotiation Administrative

Selects the network ports that match this parameter value.

### [ -autonegotiate-oper {true|false} ] - Auto-Negotiation Operational

Selects the network ports that match this parameter value.

### [ -duplex-admin {auto|half|full} ] - Duplex Mode Administrative

Selects the network ports that match this parameter value.

### [ -duplex-oper {auto|half|full} ] - Duplex Mode Operational

Selects the network ports that match this parameter value.

**[-speed-admin {auto|10|100|1000|10000|100000|40000|25000}] - Speed Administrative**

Selects the network ports that match this parameter value.

**[-speed-oper {auto|10|100|1000|10000|100000|40000|25000}] - Speed Operational**

Selects the network ports that match this parameter value.

**[-flowcontrol-admin {none|receive|send|full}] - Flow Control Administrative**

Selects the network ports that match this parameter value.

**[-flowcontrol-oper {none|receive|send|full}] - Flow Control Operational**

Selects the network ports that match this parameter value.

**[-mac <MAC Address>] - MAC Address**

Selects the network ports that match this parameter value.

**[-up-admin {true|false}] - Up Administrative**

Selects the network ports that match this parameter value.

**[-type {physical|if-group|vlan|vip|pvlan}] - Port Type**

Selects the network ports that match this parameter value.

**[-ifgrp-node <nodename>] - Interface Group Parent Node**

Selects the network ports that match this parameter value.

**[-ifgrp-port {<netport>|<ifgrp>}] - Interface Group Parent Port**

Selects the network ports that match this parameter value.

**[-ifgrp-distr-func {mac|ip|sequential|port}] - Distribution Function**

Selects the network ports that match this parameter value.

**[-ifgrp-mode {multimode|multimode\_lacp|singlemode}] - Create Policy**

Selects the network ports that match this parameter value.

**[-vlan-node <nodename>] - Parent VLAN Node**

Selects the network ports that match this parameter value.

**[-vlan-port {<netport>|<ifgrp>}] - Parent VLAN Port**

Selects the network ports that match this parameter value.

**[-vlan-tag <integer>] - VLAN Tag**

Selects the network ports that match this parameter value.

**[-remote-device-id <text>] - Remote Device ID**

Selects the network ports that match this parameter value.

**[-ipspace <IPspace>] - IPspace Name**

Use this parameter to display information only about the ports that match the IPspace you specify.

**[-broadcast-domain <Broadcast Domain>] - Broadcast Domain**

Use this parameter to display information only about the ports that match the broadcast-domain you specify.

**[-mtu-admin <integer>] - MTU Administrative**

Selects the network ports that match this parameter value.

**[-health-status {healthy|degraded}] - Port Health Status**

Use this parameter to display information only about the ports that match the health-status you specify.

**[-ignore-health-status {true|false}] - Ignore Port Health Status**

Use this parameter to display information only about the ports that match the ignore-health-status you specify.

**[-health-degraded-reasons {l2-reachability|link-flapping|crc-errors|vswitch-link}] - Port Health Degraded Reasons**

Use this parameter to display information only about the ports that match the degraded-reason you specify.

**[-vm-network-name <text>] - Virtual Machine Network Name**

Use this parameter to display information only about the ports that match the network name you specify. Google Cloud Platform only.

**[-rdma-protocols <roce>, ...] - Supported RDMA Protocols**

Use this parameter to display information only about the ports that support the specified RDMA protocols.

## Examples

The following example displays information about all network ports.

```
cluster1::> network port show
```

```
Node: node1
```

Port	IPspace	Broadcast Domain	Link	MTU	Speed(Mbps) Admin/Oper	Health Status	Ignore Health Status
e0a	Cluster	Cluster	up	9000	auto/1000	healthy	false
e0b	Cluster	Cluster	up	9000	auto/1000	healthy	false
e0c	Default	Default	up	1500	auto/1000	degraded	false
e0d	Default	Default	up	1500	auto/1000	degraded	true

```
Node: node2
```

Port	IPspace	Broadcast Domain	Link	MTU	Speed(Mbps) Admin/Oper	Health Status	Ignore Health Status
-----	-----	-----	-----	-----	-----	-----	-----

```

e0a      Cluster      Cluster      up    9000  auto/1000  healthy  false
e0b      Cluster      Cluster      up    9000  auto/1000  healthy  false
e0c      Default      Default      up    1500  auto/1000  healthy  false
e0d      Default      Default      up    1500  auto/1000  healthy  false

```

8 entries were displayed.

The following example displays health information about all network ports.

```

cluster1::> network port show -health
                                Ignore
                                Health
Node      Port      Link Status  Status Degraded Reasons
-----
node1
  e0a     up    healthy  false  -
  e0b     up    healthy  false  -
  e0c     up    degraded false  l2_reachability,
                                link_flapping
  e0d     up    degraded false  l2_reachability

node2
  e0a     up    healthy  false  -
  e0b     up    healthy  false  -
  e0c     up    healthy  false  -
  e0d     up    degraded false  -

```

8 entries were displayed.

## network port broadcast-domain add-ports

Add ports to a layer 2 broadcast domain

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

Add ports to a broadcast domain.

The IPspace of the ports added will be updated to the IPspace of the broadcast-domain. The ports will be added to the failover-group of the broadcast-domain. The MTU of the ports will be updated to the MTU of the broadcast-domain.

### Parameters

**-ipSpace <IPSpace> - IPspace Name**

The IPspace of the broadcast domain.

**-broadcast-domain <Broadcast Domain> - Layer 2 Broadcast Domain**

The broadcast domain for this port assignment.

**-ports [node>:<port], ... - List of ports**

The ports to be added to this broadcast domain.

## Examples

The following example adds the port "e0d" on node "cluster1-1" and port "e0d" on node "cluster1-2" to broadcast domain "mgmt" in IPspace "Default".

```
cluster1::network port broadcast-domain> add-ports -ipSpace Default -broadcast-domain
mgmt -ports cluster1-1:e0d, cluster1-2:e0d
```

# network port broadcast-domain create

Create a new layer 2 broadcast domain

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Create a new broadcast domain.

The IPspace of the ports added will be updated to the IPspace of the broadcast-domain. A failover-group will be generated containing the ports of the broadcast-domain. The MTU of all of the ports in the broadcast-domain will be updated to the MTU specified for the broadcast-domain.

## Parameters

**[-ipSpace <IPSpace>] - IPspace Name**

The IPspace to which the new broadcast domain belongs.

**-broadcast-domain <Broadcast Domain> - Layer 2 Broadcast Domain**

The name of the broadcast domain to be created. The name of the broadcast domain needs to be unique within the IPspace.

**-mtu <integer> - Configured MTU**

MTU of the broadcast domain.

**[-ports [node]:<port>, ...] - Ports**

The network ports to be added to the broadcast domain. Ports need to be added to the broadcast domain before interfaces can be hosted on the port. By default, no port will be added to the broadcast domain.

## Examples

The following example creates broadcast domain "mgmt" in IPspace "Default" with an MTU of 1500 and network ports e0c from node "gx1" and node "gx2".

```
cluster1::> network port broadcast-domain create -ipspace Default -broadcast-domain mgmt -mtu 1500 -ports gx1:e0c,gx2:e0c
```

# network port broadcast-domain delete

Delete a layer 2 broadcast domain

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Delete a broadcast domain that contains no ports.

## Parameters

**-ipspace <IPspace> - IPspace Name**

The IPspace to which the broadcast domain belongs

**-broadcast-domain <Broadcast Domain> - Layer 2 Broadcast Domain**

The name of the broadcast domain to be deleted.

## Examples

The following example deletes the broadcast domain "mgmt" in IPspace "Default".

```
cluster1::network port broadcast-domain> delete -ipspace Default -broadcast-domain mgmt
```

# network port broadcast-domain merge

Merges two layer 2 broadcast domains

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Merges a broadcast domain into an existing broadcast domain.

## Parameters

**-ip-space <IPspace> - IPspace Name**

The IPspace of the broadcast domain.

**-broadcast-domain <Broadcast Domain> - Layer 2 Broadcast Domain**

The merging broadcast domain.

**-into-broadcast-domain <Broadcast Domain> - Merge with This Layer 2 Broadcast Domain**

The target broadcast domain for the merge operation.

## Examples

The following example merges broadcast domain "bd-mgmt" in IPspace "Default" to broadcast domain "bd-data".

```
cluster1::network port broadcast-domain> merge -ip-space Default -broadcast-domain bd-  
mgmt -into-broadcast-domain bd-data
```

## network port broadcast-domain modify

Modify a layer 2 broadcast domain

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Modify a broadcast domain.

## Parameters

**-ip-space <IPspace> - IPspace Name**

The IPspace to which the broadcast domain belongs.

**-broadcast-domain <Broadcast Domain> - Layer 2 Broadcast Domain**

The name of the broadcast domain.

## **[-mtu <integer>] - Configured MTU**

MTU of the broadcast domain. All ports that belong to the broadcast domain are modified.

## Examples

The following example modifies the mtu attribute of broadcast domain "mgmt" in IPspace "Default" to 1500

```
cluster1::network port broadcast-domain*> modify -ipspace Default -broadcast-domain mgmt -mtu 1500
```

# network port broadcast-domain move

Move a layer 2 broadcast domain to another IPspace

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Move a broadcast domain to another IPspace.

## Parameters

### **-ipspace <IPspace> - IPspace Name**

The IPspace to which the broadcast domain belongs.

### **-broadcast-domain <Broadcast Domain> - Layer 2 Broadcast Domain**

The name of the broadcast domain.

### **-to-ipspace <IPspace> - Name of the destination IPspace**

The name of the destination IPspace.

## Examples

The following example moves the broadcast domain named "mgmt" from IPspace "Default" to IPspace "Default-1".

```
cluster1::network port broadcast-domain> move -ipspace Default -broadcast-domain mgmt -to-ipspace Default-1
```

# network port broadcast-domain remove-ports

Remove ports from a layer 2 broadcast domain

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Remove port assignments from a broadcast domain.

## Parameters

**-ipSpace <IPspace> - IPspace Name**

The IPspace of the broadcast domain.

**-broadcast-domain <Broadcast Domain> - Layer 2 Broadcast Domain**

The broadcast domain of the ports.

**-ports [node>:<port], ... - List of ports**

The ports to removed from the broadcast-domain.

## Examples

The following example removes port "e0d" on node "cluster1-1" and port "e0d" on node "cluster1-2" from broadcast domain "mgmt" in IPspace "Default".

```
cluster1::network port broadcast-domain> remove-ports -ipSpace Default -broadcast  
-domain mgmt -ports cluster1-1:e0d, cluster1-2:e0d
```

# network port broadcast-domain rename

Rename a layer 2 broadcast domain

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Rename a broadcast domain.

## Parameters

**-ipSpace <IPspace> - IPspace Name**

The IPspace to which the broadcast domain belongs.

**-broadcast-domain <Broadcast Domain> - Layer 2 Broadcast Domain**

The name of the broadcast domain.

**-new-name <text> - New Name**

The new name of the broadcast domain.

## Examples

The following example renames the broadcast domain named "mgmt" to "mgmt2" in IPspace "Default".

```
cluster1::network port broadcast-domain> rename -ipspace Default -broadcast-domain  
mgmt -new-name mgmt2
```

## network port broadcast-domain show

Display layer 2 broadcast domain information

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Display broadcast domain information.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[ -ipspace <IPspace> ] - IPspace Name**

Selects the broadcast domains that match the IPspace name.

**[ -broadcast-domain <Broadcast Domain> ] - Layer 2 Broadcast Domain**

Selects the broadcast domains that match the broadcast domain name.

**[ -mtu <integer> ] - Configured MTU**

Selects the broadcast domains that match the MTU value. This field is the MTU that was configured by the user, which might be different from the operational MTU.

**[-ports [node>:<port],...] - Ports**

Selects the broadcast domains that contain the network ports. For example, node1:e0a will display broadcast domains that contain node1:e0a network port.

**[-port-update-status {complete|in-progress|error|overridden-while-offline}] - Port Update Status**

Selects the broadcast domains that contain the network port status. For example, specifying "error" will display broadcast domains that contain "Error" network port status.

**[-port-update-status-details <text>,...] - Status Detail Description**

Selects the broadcast domains that contain the network port status detail text.

**[-port-update-status-combined {complete|in-progress|error|overridden-while-offline}] - Combined Port Update Status**

Selects the broadcast domains that contain the combined network port status. For example, specifying "error" will display broadcast domains that contain a combined network port status of "Error".

**[-failover-groups <failover-group>,...] - Failover Groups**

Selects the broadcast domains that contain the failover groups.

**[-subnet-names <subnet name>,...] - Subnet Names**

Selects the broadcast domains that contain the subnet name or names.

**[-is-vip {true|false}] - Is VIP Broadcast Domain**

Selects the broadcast domains that match a specific "is-vip" flag. Specifying "true" matches only broadcast domains associated with the Virtual IP feature; "false" matches only broadcast domains that do not.

## Examples

The following example displays general information about broadcast domains.

```
cluster1::> network port broadcast-domain show
IPspace Broadcast
Name    Domain Name    MTU    Port List
-----
Cluster Cluster      9000
                node1:e0a      complete
                node1:e0b      complete
Default Default      1500
                node1:e0c      complete
                node1:e0d      complete
2 entries were displayed.
```

# network port broadcast-domain split

Splits a layer 2 broadcast domain into two layer 2 broadcast domains.

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Splits ports from a broadcast domain into a new broadcast domain.

The following restrictions apply to this command:

- If the ports are in a failover group, all ports in the failover group must be provided. Use [network interface failover-groups show](#) to see which ports are in failover groups.
- If the ports have LIFs associated with them, the LIFs cannot be part of a subnet's ranges and the LIF's **curr-port** and **home-port** must both be provided. Use [network interface show`-fieldssubnet-name , home-node , home-port , curr-node , curr-port](#) to see which ports have LIFs associated with them and whether the LIFs are part of a subnet's ranges. Use [network subnet remove-ranges](#) with the LIF's IP address and ``-force-update-lif-associations` set to **true** to remove the LIF's association with a subnet.

## Parameters

**-ipSPACE <IPSPACE> - IPSPACE Name**

The IPSPACE of the broadcast domain.

**-broadcast-domain <Broadcast Domain> - Layer 2 Broadcast Domain**

The broadcast domain to split.

**-new-broadcast-domain <Broadcast Domain> - New Layer 2 Broadcast Domain Name**

The new broadcast domain.

**-ports [*node*>:<port>],... - List of Ports**

The ports to be split from this broadcast domain.

## Examples

The following example splits port "e0d" on node "cluster1-1" and port "e0d" on node "cluster1-2" from broadcast domain "bd-mgmt" in IPSPACE "Default" to broadcast domain "bd-data".

```
cluster1::> network port broadcast-domain split -ipSPACE Default -broadcast-domain bd-  
mgmt -new-broadcast-domain bd-data -ports cluster1-1:e0d, cluster1-2:e0d
```

# network port ifgrp add-port

Add a port to an interface group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **network port ifgrp add-port** command adds a network port to a port interface group. The port interface group must already exist. You can create a port interface group by using the [network port ifgrp create](#) command.

The following restrictions apply to port interface groups:

- A port that is already a member of a port interface group cannot be added to another port interface group.
- Cluster ports and management ports cannot be in a port interface group.
- A port to which a logical interface is already bound cannot be added to a port interface group.
- A port that already has an assigned failover role cannot be added to a port interface group.
- A VLAN port cannot be added to a port interface group.
- A port which attaches to a VLAN cannot be added to a port interface group.
- An interface group port cannot be added to a port interface group.
- A port that is assigned to a broadcast domain cannot be added to a port interface group.
- All ports in a port interface group must be physically located on the same node.

## Parameters

**-node {<nodename>|local} - Node**

The node on which the port interface group is located.

**-ifgrp <ifgrp name> - Interface Group Name**

The port interface group to which a port is to be added.

**-port <netport> - Specifies the name of port.**

The network port that is to be added to the port interface group.

**[-skip-broadcast-domain-placement <true>] - Skip Placement Into Broadcast Domain**

When specified along with the first port added to the ifgrp, the ifgrp will not be placed into any broadcast domain.

## Examples

The following example adds port e0c to port interface group a1a on a node named node1:

```
cluster1::> network port ifgrp add-port -node node1 -ifgrp a1a -port e0c
```

## Related Links

- [network port ifgrp create](#)

# network port ifgrp create

Create a port interface group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **network port ifgrp create** command creates a port interface group. See the documentation for the [network port ifgrp add-port](#) command for a list of restrictions on creating port interface groups.

## Parameters

**-node {<nodename>|local} - Node**

The node on which the port interface group will be created.

**-ifgrp <ifgrp name> - Interface Group Name**

The name of the port interface group that will be created. Port interface groups must be named using the syntax "a<number><letter>", where <number> is an integer in the range [0-999] without leading zeros and <letter> is a lowercase letter. For example, "a0a", "a0b", "a1c", and "a2a" are all valid port interface group names.

**-distr-func {mac|ip|sequential|port} - Distribution Function**

The distribution function of the port interface group that will be created. Valid values are:

- mac - Network traffic is distributed based on MAC addresses
- ip - Network traffic is distributed based on IP addresses
- sequential - Network traffic is distributed in round-robin fashion from the list of configured, available ports

- port - Network traffic is distributed based on the transport layer (TCP/UDP) ports

### **-mode {multimode|multimode\_lacp|singlemode} - Create Policy**

The create policy for the interface group that will be created. Valid values are:

- multimode - Bundle multiple member ports of the interface group to act as a single trunked port
- multimode\_lacp - Bundle multiple member ports of the interface group using Link Aggregation Control Protocol
- singlemode - Provide port redundancy using member ports of the interface group for failover

## Examples

The following example creates a port interface group named a0a on node node0 with a distribution function of ip:

```
cluster1::> network port ifgrp create -node node0 -ifgrp a0a -distr-func ip -mode multimode
```

## Related Links

- [network port ifgrp add-port](#)

# network port ifgrp delete

Destroy a port interface group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **network port ifgrp delete** command destroys a port interface group.

When you delete an interface group port, it is automatically removed from failover rules and groups to which it belongs.

## Parameters

### **-node {<nodename>|local} - Node**

The node on which the port interface group is located.

### **-ifgrp <ifgrp name> - Interface Group Name**

The port interface group that will be deleted.

## Examples

The following example deletes port interface group a0b from a node named node0.

```
cluster1::> network port ifgrp delete -node node0 -ifgrp a0b
```

## network port ifgrp remove-port

Remove a port from an interface group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `network port ifgrp remove-port` command removes a network port from a port interface group.

## Parameters

**-node {<nodename>|local} - Node**

The node on which the port interface group is located.

**-ifgrp <ifgrp name> - Interface Group Name**

The port interface group from which a port will be removed.

**-port <netport> - Specifies the name of port.**

The network port that will be removed from the port interface group.

## Examples

The following example removes port e0d from port interface group a1a on a node named node1:

```
cluster1::> network port ifgrp remove-port -node node1 -ifgrp a1a -port e0d
```

## network port ifgrp show

Display port interface groups

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `network port ifgrp show` command displays information about port interface groups. By default,

it displays information about all port interface groups on all nodes in the cluster.

## Parameters

### **{ [-fields <fieldname>, ...]**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

### **[-instance ]}**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

### **[-node {<nodename>|local}] - Node**

Selects the port interface groups that match this parameter value. Use this parameter with the **-ifgrp** parameter to select information about a specific port interface group.

### **[-ifgrp <ifgrp name>] - Interface Group Name**

Selects the port interface groups that match this parameter value. Use this parameter with the **-node** parameter, to select information about a specific port interface group.

### **[-distr-func {mac|ip|sequential|port}] - Distribution Function**

Selects the port interface groups that match this parameter value.

### **[-mode {multimode|multimode\_lacp|singlemode}] - Create Policy**

Selects the port interface groups that match this parameter value.

### **[-mac <MAC Address>] - MAC Address**

Selects the port interface groups that match this parameter value.

### **[-activeports {full|partial|none}] - Port Participation**

Selects the port interface groups that match this parameter value. The value "partial" indicates that some but not all of the port interface group's ports are active. the value "full" indicates that all of the port interface group's ports are active.

### **[-ports {<netport>|<ifgrp>}] - Network Ports**

Selects the port interface groups that match this parameter value.

### **[-up-ports {<netport>|<ifgrp>}] - Up Ports**

Selects the port interface groups that match this parameter value. Displays only the ports that are up.

### **[-down-ports {<netport>|<ifgrp>}] - Down Ports**

Selects the port interface groups that match this parameter value. Displays only the ports that are down.

## Examples

The following example displays information about all port interface groups.

```
cluster1::> network port ifgrp show
  Port      Distribution      Active
Node  ifgrp  Function  MAC Address  Ports  Ports
-----
node0
  a0a    ip        b8:f8:7a:20:00 partial e0c
node1
  a1a    ip        07:26:60:02:00 full    e0d
```

## network port reachability repair

Repair reachability

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

Repair network port configuration to match the detected reachable broadcast domain. If the reachability scan has completed with a reachability-status of *misconfigured-reachability*, meaning the network port does not have reachability to its configured broadcast domain, but has reachability to another broadcast domain, then repairing the network port's reachability will assign the port to the detected broadcast domain. Similarly, if the reachability scan has completed with a reachability status of *no-reachability*, then repairing the network port's reachability will assign the port to an empty broadcast domain. LIFs configured on the port will be adjusted to be configured on another port in their current broadcast domain if possible. Vlans on the specified port that do not have reachability to their configured broadcast domain will be removed. If the port was part of an ifgrp, the port will be removed from the ifgrp. If the port is not configured on a broadcast domain and has no reachability to any existing broadcast domains, it will be configured in a newly created broadcast domain.

### Parameters

**-node {<nodename>|local} - Node**

Selects the node on which the port resides.

**-port <netport> - Port**

Selects the port on which to repair configuration.

## Examples

The following example applies the scanned broadcast domain reachability information to the specified port's configuration.

```
cluster1::> network port reachability repair -node node1 -port e0c
```

## network port reachability scan

Perform a reachability scan

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

Scan network port configuration to detect reachable broadcast domains.

### Parameters

**-node {<nodename>|local} - Node**

Selects the node on which the port resides.

**-port <netport> - Port**

Selects the port on which to scan broadcast domain reachability.

## Examples

The following example applies the scanned broadcast domain reachability information to the specified port's configuration.

```
cluster1::> network port reachability scan -node node1 -port e0c
```

## network port reachability show

Display Reachability Status

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

Display broadcast domain reachability information for the specified port. If the port is discovered, via a layer 2 reachability scan, to have reachability to broadcast domains other than the one on which it

is expected, the command will list the reachable broadcast domains and an appropriate reachability status message. If the reachable broadcast domain matches the expected one, the reachability status is displayed as Ok.

## Parameters

### { [-fields <fieldname>, ...]

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

### [-detail ]

When true, additional details regarding which broadcast domains have been found to be reachable from the specified network port are displayed.

### [-instance ]}

If you specify the **-instance** parameter, the command displays detailed information about all fields.

### [-node {<nodename>|local}] - Node

Selects the node on which the port resides.

### [-port <netport>] - Port

Selects the port for which to display broadcast domain reachability information.

### [-expected-broadcast-domain [IPspace>:<Broadcast Domain]] - Expected Broadcast Domain

The IPspace and broadcast domain currently assigned to the network port. If the specified port is an ifgrp member, the expected broadcast domain is the IPspace and broadcast domain currently assigned to the parent ifgrp.

### [-reachable-broadcast-domains [IPspace>:<Broadcast Domain], ...] - Reachable Broadcast Domains

The name of the IPspaces and broadcast domains that have reachability to the specified port, as discovered by a layer 2 reachability scan.

### [-reachability-status {unknown|ok|no-reachability|misconfigured-reachability|multi-domain-reachability|internal-error}] - Reachability Status

The status of the broadcast domain reachability for the specified port. "Ok" if the expected broadcast domain matches the reachable broadcast domains, i.e., the port can reach other ports in the expected broadcast domain, but no ports configured in other broadcast domains. "No-reachability" if the port cannot reach any ports in the expected broadcast domain, and also cannot reach any ports in any other broadcast domains. "Misconfigured-reachability" if the port cannot reach any ports in the expected broadcast domain, but can reach ports in one other broadcast domain. "Multi-domain-reachability" if the port can reach other ports configured in multiple broadcast domains. "Unknown" if the port has not been link-up long enough for reachability to be determined.

### [-unreachable-ports [node>:<port], ...] - Unreachable Ports

The list of network ports that are expected in the same broadcast domain as the specified port

but cannot be reached, either because those ports are down or because there is no network connectivity to those ports.

### **[-unexpected-ports [node>:<port],...] - Unexpected Ports**

The list of network ports that are not expected in the same broadcast domain yet have network connectivity to the specified port.

## Examples

The following example displays the broadcast domain reachability for the specified port.

```
cluster1::> network port reachability show -node node1 -port e0d
network port reachability show)
ode          Port      Expected Reachability      Reachability Status
-----
ode1         e0d        Default:Default            ok
```

The following example displays the detailed reachability for the 'e0d' port when it has misconfigured-reachability, i.e., it cannot reach the other 'e0d' port in the expected broadcast domain 'Default:Default', but can reach the 'e0c' ports configured in the 'Default:Default-3' broadcast domain.

```
cluster1::> network port reachability show -node node1 -port e0d -detail
network port reachability show)
ode          Port      Expected Reachability      Reachability Status
-----
ode1         e0d        Default:Default            misconfigured-reachability
Actual Reachability: Default:Default-3
Unreachable Ports: node2:e0d
Unexpected Ports: node2:e0c, node1:e0c
```

The following example displays the detailed reachability for the 'e0d' port when it has multi-domain-reachability, i.e., it can reach the other 'e0d' port in the expected broadcast domain 'Default:Default', but can also reach the 'e0c' ports configured in the 'Default:Default-3' broadcast domain.

```
cluster1::> network port reachability show -node node1 -port e0d -detail
network port reachability show)
ode          Port      Expected Reachability      Reachability Status
-----
ode1         e0d        Default:Default            multi-domain-reachability
Actual Reachability: Default:Default,
                    Default:Default-3
Unreachable Ports: -
Unexpected Ports: node2:e0c, node1:e0c
```

The following example displays the detailed reachability for the 'e0d' port when it has no-

reachability, i.e., it cannot reach the other 'e0d' port in the expected broadcast domain 'Default:Default', and also cannot reach any other ports configured in broadcast domains.

```
cluster1::> network port reachability show -node node1 -port e0d -detail
network port reachability show)
ode      Port      Expected Reachability      Reachability Status
-----
ode1     e0d      Default:Default            no-reachability
Actual Reachability: -
Unreachable Ports: node2:e0d
Unexpected Ports: -
```

## network port vip create

Create a VIP port

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

The **network port vip create** command creates a VIP port in the specified IPspace on the specified node. Only one VIP port can be created per IPspace on the given node.

### Parameters

**-node {<nodename>|local} - Node**

The node where the VIP port should be created.

**-port <netport> - Network Port**

The name of the VIP port to be created in the format v<slot-number><port-letter>

**-ipspace <IPspace> - IPspace Name**

The IPspace where the VIP port should be created. The default value for this parameter is "Default", which identifies the default IPspace.

### Examples

This example shows how to create a VIP port named v0a in ipspace ips on node1.

```
cluster1::> network port vip create -node node1 -port v0a -ipspace ips
```

# network port vip delete

Delete a VIP port

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `network port vip delete` command deletes a VIP port.

## Parameters

**-node {<nodename>|local} - Node**

The node associated with the VIP port to be deleted.

**-port <netport> - Network Port**

The name of the VIP port to be deleted.

## Examples

This example shows how to delete VIP Port v0a on node1.

```
cluster1::> network port vip delete -node node1 -port v0a
```

# network port vip show

Display VIP ports

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `network port vip show` command displays information about VIP ports.

## Parameters

**{ [-fields <fieldname>, ... ]**

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

**[ -instance ] }**

If you specify the `-instance` parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node**

This parameter selects the VIP ports that match the specified node.

**[-port <netport>] - Network Port**

This parameter selects the VIP ports that match the specified port.

**[-ipSpace <IPspace>] - IPspace Name**

This parameter selects the VIP ports that match the specified IPspace.

## Examples

The example below shows VIP port v0a is created in IPspace ips on node1.

```
cluster1::> network port vip show
Node   VIP Port IPspace
-----
node1  v0a     ips
```

# network port vlan create

Create a virtual LAN (VLAN)

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **network port vlan create** command attaches a VLAN to a network port on a specified node.

## Parameters

**-node {<nodename>|local} - Node**

The node to which the VLAN is to be attached.

You cannot attach a VLAN to a cluster port.

**{ -vlan-name {<netport>|<ifgrp>} - VLAN Name**

The name of the VLAN that is to be attached. This name should be a combination of the name of the port or interface group and the VLAN ID, with a hyphen between, such as "e1c-80".

**[-port {<netport>|<ifgrp>} - Associated Network Port**

The network port to which the VLAN is to be attached.

**-vlan-id <integer> - Network Switch VLAN Identifier }**

The ID tag of the created VLAN.

**[-skip-broadcast-domain-placement <true>] - Skip Placement Into Broadcast Domain**

When specified, the VLAN will not be placed into any broadcast domain.

## Examples

This example shows how to create VLAN e1c-80 attached to network port e1c on node1.

```
cluster1::> network port vlan create -node node1 -vlan-name e1c-80
```

## network port vlan delete

Delete a virtual LAN (VLAN)

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **network port vlan delete** command deletes a VLAN from a network port.

When you delete a VLAN port, it is automatically removed from all failover rules and groups that use it.

## Parameters

**-node {<nodename>|local} - Node**

The node from which the VLAN is to be deleted.

**{ -vlan-name {<netport>|<ifgrp>} - VLAN Name**

The name of the VLAN that is to be deleted

**| -port {<netport>|<ifgrp>} - Associated Network Port**

The network port to which the VLAN is to be attached.

**-vlan-id <integer> - Network Switch VLAN Identifier }**

The ID tag of the deleted VLAN.

## Examples

This example shows how to delete VLAN e1c-80 from network port e1c on node1.

```
cluster1::> network port vlan delete -node node1 -vlan-name e1c-80
```

# network port vlan show

Display virtual LANs (VLANs)

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **network port vlan show** command displays information about network ports that are attached to VLANs. The command output indicates any inactive links and lists the reason for the inactive status.

If the operational duplex mode and speed cannot be determined (for instance, if the link is down), they are listed as **undef**, meaning undefined.

## Parameters

{ [-fields <fieldname>, ... ] }

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[ [-instance ] ] }

If you specify the **-instance** parameter, the command displays detailed information about all fields.

[ -node {<nodename>|local} ] - Node

Selects the VLAN network ports that match this parameter value.

{ [-vlan-name {<netport>|<ifgrp>} ] - VLAN Name

Selects the VLAN network ports that match this parameter value.

[ [-port {<netport>|<ifgrp>} ] - Associated Network Port

Selects the VLAN network ports that match this parameter value. If neither this parameter nor **-name** are used, the command displays information about all network ports.

[ -vlan-id <integer> ] - Network Switch VLAN Identifier }

Selects the VLAN network ports that match this parameter value.

[ -mac <MAC Address> ] - MAC address

Selects the VLAN network ports that match this parameter value.

## Examples

The example below shows VLAN e1b-70 attached to port e1b on node1.

```
cluster1::> network port vlan show
Network Network
```

Node	VLAN Name	Port	VLAN ID	MAC Address
node1	e1b-70	e1b	70	00:15:17:76:7b:69

## network qos-marking modify

Modify the QoS marking values

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **network qos-marking modify** command modifies the QoS marking values for different protocols, for each IPspace.

### Parameters

**-ipSPACE <IPspace> - IPspace name**

Use this parameter to specify the IPspace for which the QoS marking entry is to be modified.

**-protocol <text> - Protocol**

Use this parameter to specify the protocol for which the QoS marking entry is to be modified. The possible values are NFS, CIFS, iSCSI, NVMe-TCP, SnapMirror, SnapMirror-Sync, NDMP, FTP, HTTP-admin, HTTP-filesrv, SSH, Telnet, and SNMP.

**[-dscp <integer>] - DSCP Marking Value**

Use this parameter to specify the DSCP value. The possible values are 0 to 63.

**[-is-enabled {true|false}] - Is QoS Marking Enabled**

Use this parameter to enable or disable the QoS marking for the specified protocol and IPspace.

### Examples

The following example modifies the QoS marking entry for the NFS protocol in the Default IPspace:

```
cluster1::> network qos-marking modify -ipSPACE Default -protocol NFS -dscp 10 -is-enabled true
```

## network qos-marking show

Display the QoS marking values

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **network qos-marking show** command displays the QoS marking values for different protocols, for each IPspace.

## Parameters

**{ [-fields <fieldname>, ... ] }**

Use this parameter to display only certain fields of the QoS marking table.

**[ [-instance ] ] }**

Use this parameter to display all the fields of the QoS marking table.

**[-ipSPACE <IPspace>] - IPspace name**

Use this parameter to display the QoS marking entries for the specified IPspace.

**[-protocol <text>] - Protocol**

Use this parameter to display the QoS marking entries for the specified protocol. The possible values are NFS, CIFS, iSCSI, NVMe-TCP, SnapMirror, SnapMirror-Sync, NDMP, FTP, HTTP-admin, HTTP-filesrv, SSH, Telnet, and SNMP.

**[-dscp <integer>] - DSCP Marking Value**

Use this parameter to display the QoS marking entries matching the specified DSCP value. The possible values are 0 to 63.

**[-is-enabled {true|false}] - Is QoS Marking Enabled**

Use this parameter to display the QoS marking entries matching the specified flag.

## Examples

The following example displays the QoS marking entries for the Default IPspace.

```
cluster1::> network qos-marking show -ipSPACE Default
IPspace          Protocol          DSCP  Enabled?
-----
Default
                CIFS              10    false
                FTP              48    false
                HTTP-admin       48    false
                HTTP-filesrv    10    false
                NDMP         10    false
                NFS         10    true
                SNMP         48    false
                SSH         48    false
                SnapMirror   10    false
                SnapMirror-Sync 10    false
                Telnet      48    false
```

iSCSI	10	false
NVMe-TCP	10	false

12 entries were displayed.

## network route create

Create a static route

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

### Description

The **network route create** command creates a static route within a Vserver.

### Parameters

**-vserver <vserver> - Vserver Name**

Use this parameter to specify the Vserver on which the route is to be created.

**-destination <IP Address/Mask> - Destination/Mask**

Use this parameter to specify the IP address and subnet mask of the route's destination. The format for this value is: address, slash ("/"), mask. **0.0.0.0/0** is a valid destination value to create default IPv4 route. And **::/0** is a valid destination value to create default IPv6 route

**-gateway <IP Address> - Gateway**

Use this parameter to specify the IP address of the gateway server leading to the route's destination.

**[-metric <integer>] - Metric**

Use this parameter to specify the metric of the route.

### Examples

The following example creates default routes within Vserver vs0 for IPv4 and IPv6.

```
cluster1::> network route create -vserver vs0 -destination 0.0.0.0/0 -gateway
10.61.208.1
cluster1::> network route create -vserver vs0 -destination ::/0 -gateway 3ffe:1::1
```

## network route delete

Delete a static route

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `network route delete` command deletes a static route from a Vserver.

## Parameters

### `-vserver <vserver>` - Vserver Name

Use this parameter to specify the Vserver on which the route is to be deleted.

### `-destination <IP Address/Mask>` - Destination/Mask

Use this parameter to specify the IP address and subnet mask of the route's destination. The format for this value is: address, slash ("/"), mask. For example, `0.0.0.0/0` is a correctly formatted value for the `-destination` parameter.

### `-gateway <IP Address>` - Gateway

Use this parameter to specify the gateway on which the route is to be deleted.

## Examples

The following example deletes a route within Vserver `vs0` for destination `0.0.0.0/0`.

```
cluster1::network route delete -vserver vs0 -destination 0.0.0.0/0
```

## network route show-lifs

Show the Logical Interfaces for each route entry

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `network route show-lifs` command displays the association of static routes and Logical Interfaces (LIFs) within one or more Vservers. You can view routes within specified Vservers, routes with specified destinations, and routes with specified gateways.

## Parameters

`{ [-fields <fieldname>, ...]`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

**[`-instance`] }**

If you specify the `-instance` parameter, the command displays detailed information about all fields.

**[`-vserver <vserver>`] - Vserver Name**

Use this parameter to display only routes that have the specified Vserver as their origin.

**[`-destination <IP Address/Mask>`] - Destination/Mask**

Use this parameter to display only routes that have the specified IP address and subnet mask as their destination. The format for this value is: address, slash ("/"), mask. For example, `0.0.0.0/0` is a valid value for the `-destination` parameter.

**[`-gateway <IP Address>`] - Gateway**

Use this parameter to display only routes that have the specified IP address as their gateway.

**[`-lifs <lif-name>,...`] - Logical Interfaces**

Use this parameter to display only the routes that are associated with the specified Logical Interfaces (LIFs).

**[`-address-family {ipv4|ipv6|ipv6z}`] - Address Family**

Use this parameter to display only the routes that belong to specified address family.

## network route show

Display static routes

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **network route show** command displays a group of static routes within one or more Vservers. You can view routes within specified Vservers, routes with specified destinations, and routes with specified gateways.

## Parameters

**{ [`-fields <fieldname>,...`] }**

Use this parameter to display only certain fields of the routing tables.

**[`-instance`] }**

Use this parameter to display all fields of the routing tables.

**[`-vserver <vserver>`] - Vserver Name**

Use this parameter to display only routes that have the specified Vserver as their origin.

**[-destination <IP Address/Mask>] - Destination/Mask**

Use this parameter to display only routes that have the specified IP address and subnet mask as their destination. The format for this value is: address, slash ("/"), mask. The example below has **0.0.0.0/0** as a valid value for the -destination parameter.

**[-gateway <IP Address>] - Gateway**

Use this parameter to display only routes that have the specified IP address as their gateway.

**[-metric <integer>] - Metric**

Use this parameter to display only routes that have the specified metric.

**[-ipSPACE <IPspace>] - IPspace Name**

Use this parameter to optionally specify the IPspace associated with the Vserver. This parameter can be used in conjunction with the Vserver parameter in order to configure the same route across multiple Vservers within an IPspace.

**[-address-family {ipv4|ipv6|ipv6z}] - Address family of the route**

Use this parameter to display only the routes that have the specified address-family.

## Examples

The following example displays information about all routing groups.

```
cluster1::> network route show
(network route show)
Server          Destination      Gateway          Metric
-----
node1
                0.0.0.0/0       10.61.208.1     20
node2
                0.0.0.0/0       10.61.208.1     20
vs0
                0.0.0.0/0       10.61.208.1     20
3 entries were displayed.
```

## network route active-entry show

Display active routes

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

The **network route active-entry show** command displays installed routes on one or more nodes. You can view routes within specified nodes, within specified Vservers, routes in specified subnet groups,

and routes with specified destinations.

## Parameters

### { [-fields <fieldname>, ... ] }

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

### [ [-verbose ] ]

Use this parameter to display the reference count, use, interface, and Path MTU fields.

### [ [-instance ] ] }

If you specify the **-instance** parameter, the command displays detailed information about all fields.

### [ -vserver <vserver> ] - Vserver Name

Displays the routes that have the specified Vserver as their origin.

### [ -node {<nodename>|local} ] - Node

Displays the routes from the specified node.

### [ -address-type {ipv4|ipv6|ipv6z} ] - Address Family

Displays the routes that have the specified IP address type.

### [ -subnet-group <IP Address/Mask> ] - Subnet Group

Displays the group of routes that belong to the specified subnet. Routes within the specified subnet group are used first before the default set. The "default" subnet group is a system-provided set of default routes.

### [ -destination <text> ] - Destination

Displays the routes that have the specified IP address or subnet as their destination. The format for the subnet is: <address>/<mask>. IPv6 address includes the scope value after percentage ("%"). 0.0.0.0/0, 169.254.4.60, ff02::%e0a/32 and fe80::250:56ff:fea6:db7c%e0b are valid values for this parameter.

### [ -interface <text> ] - Interface Name

Displays the routes that use the specified interface to transmit packets to the destination. A valid interface has the format of {<netport>|<ifgrp>}, such as "e0a", "e0a-1" and "a0a", or it can be a loopback interface, such as "lo" and "losk".

### [ -route-interface-address <text> ] - Route Interface Address

Displays the routes that use the specified IP address on the transmit interface.

### [ -gateway <text> ] - Route gateway

Displays the routes that have the specified gateway. The gateway can be an IP address, such as "10.10.2.1" and "fe80::1%lo", MAC address, such as "0:5:73:a0:1:7" or refer to a local link, such as "link#3".

**[-metric <integer>] - Metric**

Displays the routes that have the specified metric.

**[-flags <text>] - Flags**

Displays the routes that have the specified flags. The type string for "-flags" needs to be one or more of the following {U|G|H|R|D|S|1|2|L|C} in the order shown.

- U - Usable
- G - Gateway
- H - Host
- R - Reject
- D - Dynamic
- S - Static
- 1 - Protocol1
- 2 - Protocol2
- L - Linfo
- C - Clone

Multiple values can be specified (for example: UHL).

**[-reference-count <integer>] - Reference Count**

Displays the routes that have the specified reference count in the system.

**[-lookup-count <integer>] - Lookup Count**

Displays the routes that have the specified use count (the count of lookups for the route).

**[-path-mtu <integer>] - Path MTU**

Displays the routes that have the specified path maximum transmission unit.

## Examples

The following example displays active routes on all nodes in Vserver vs0 with subnet-group 10.10.10.0/24.

```
cluster1::*> network route active-entry show -vserver vs0 -subnet-group 10.10.10.0/24
(network route active-entry show)
```

```
Vserver: vs0
```

```
Node: node1
```

```
Subnet Group: 10.10.10.0/24
```

Destination	Gateway	Interface	Metric	Flags
default	10.10.10.1	e0c	0	UGS

```
Vserver: vs0
```

```

Node: node2
Subnet Group: 10.10.10.0/24
Destination          Gateway          Interface      Metric  Flags
-----
default              10.10.10.1     e0c            0      UGS
2 entries were displayed.

```

## network subnet add-ranges

Add new address ranges to a subnet

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

Add new address ranges to a subnet.

All addresses in a range must be the same address family (IPv4 or IPv6) and must have the same subnet mask. Ranges that overlap or are next to existing ranges will be merged with the existing ranges.

### Parameters

**-ip-space <IPspace> - IPspace Name**

The IPspace in which the range resides.

**-subnet-name <subnet name> - Subnet Name**

The name of the subnet.

**-ip-ranges {<ipaddr>|<ipaddr>-<ipaddr>} - IP Ranges**

The list of ranges to add to the subnet.

**[-force-update-lif-associations <true>] - Force Update LIF Associations**

This command will fail if any service processor interfaces or network interfaces are using the IP addresses in the ranges provided. Using this parameter will associate any manually addressed interfaces with the subnet and will allow the command to succeed.

### Examples

The following example allocates addresses for subnet **s1** in IPspace **Default** .

```

cluster1::> network subnet add-ranges -ip-space Default -subnet-name s1
           -ip-ranges "10.98.1.20-10.98.1.30, 10.98.1.35, 10.98.1.40-10.98.1.49"

```

# network subnet create

Create a new layer 3 subnet

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Create a new subnet.

## Parameters

### **[-ip-space <IPspace>] - IPspace Name**

The IPspace to which the new subnet belongs.

### **-subnet-name <subnet name> - Subnet Name**

The name of the subnet to be created. The name of the subnet needs to be unique within the IPspace.

### **-broadcast-domain <Broadcast Domain> - Broadcast Domain**

The broadcast domain to which the new subnet belongs.

### **-subnet <IP Address/Mask> - Layer 3 Subnet**

The address and mask of the subnet.

### **[-gateway <IP Address>] - Gateway**

The gateway of the subnet.

### **[-ip-ranges {<ipaddr>|<ipaddr>-<ipaddr>}] - IP Addresses or IP Address Ranges**

The IP ranges associated with this subnet.

### **[-force-update-lif-associations <true>] - Change the subnet association**

This command will fail if any service processor interfaces or network interfaces are using the IP addresses in the ranges provided. Using this parameter will associate any manually addressed interfaces with the subnet and will allow the command to succeed.

## Examples

The following examples create subnets named **s1** and **s6** in IPspace **Default** .

```
cluster1::> network subnet create -ip-space Default -broadcast-domain bd1 -subnet-name
s1
    -subnet 192.168.1.0/24 -gateway 192.168.1.1 -ip-ranges "192.168.1.1-192.168.1.100,
192.168.1.112, 192.168.1.145"
```

```
cluster1::> network subnet create -ip-space Default -broadcast-domain bd1 -subnet-name
s6
      -subnet 3FFE::/64 -gateway 3FFE::1 -ip-ranges "3FFE::10-3FFE::20"
```

## network subnet delete

Delete an existing subnet object

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

Delete a subnet that contains no ports.

### Parameters

**-ip-space <IPspace> - IPspace Name**

The IPspace to which the subnet belongs.

**-subnet-name <subnet name> - Subnet Name**

The name of the subnet to be deleted.

**[-force-update-lif-associations <true>] - Change the subnet association**

This command will fail if the subnet has ranges containing any existing service processor interface or network interface IP addresses. Setting this value to true will remove the network interface associations with the subnet and allow the command to succeed. However, it will not affect service processor interfaces.

### Examples

The following example deletes subnet **s1** in IPspace **Default**.

```
cluster1::> network subnet delete -ip-space Default -subnet-name s1
```

## network subnet modify

Modify a layer 3 subnet

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Modify a subnet.

## Parameters

### **-ipSPACE <IPspace> - IPspace Name**

The IPspace to which the subnet belongs.

### **-subnet-name <subnet name> - Subnet Name**

The name of the subnet to modify.

### **[-subnet <IP Address/Mask>] - Layer 3 Subnet**

The new address and mask of the subnet.

### **[-gateway <IP Address>] - Gateway**

The new gateway address.

### **[-ip-ranges {<ipaddr>|<ipaddr>-<ipaddr>}] - IP Addresses or IP Address Ranges**

The new IP ranges for this subnet.

### **[-force-update-lif-associations <true>] - Change the subnet association**

This command will fail if any existing service processor interfaces or network interfaces are using IP addresses in the IP ranges being added. It will also fail if any existing service processor interfaces or network interfaces are using IP addresses in the IP ranges being removed. Using this parameter will associate the interfaces with the IP addresses in the ranges being added to the subnet. It will also remove the subnet's association with the interfaces with IP addresses in the IP ranges being removed and will allow the command to succeed.

## Examples

The following example modifies the subnet address and gateway.

```
cluster1::> network subnet modify -ipSPACE Default -subnet-name s1 -subnet  
192.168.2.0/24 -gateway 192.168.2.1
```

## network subnet remove-ranges

Remove address ranges from a subnet

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Remove address ranges from a subnet.

## Parameters

### -ipSPACE <IPspace> - IPspace Name

The IPspace in which the range resides.

### -subnet-name <subnet name> - Subnet Name

The name of the subnet.

### -ip-ranges {<ipaddr>|<ipaddr>-<ipaddr>} - IP Ranges

IP ranges to remove.

### [-force-update-lif-associations <true>] - Force Update LIF Associations

This command will fail if any existing service processor interfaces or network interfaces are using IP addresses in the ranges provided. Using this parameter will remove the subnet's association with those interfaces and allow the command to succeed.

## Examples

The following example removes an address range with starting address of **10.98.1.1** from subnet **s1** in IPspace **Default**.

```
cluster1::> network subnet remove-ranges -ipSPACE Default -subnet-name s1
-ip-ranges "10.98.1.1-10.98.1.30"
```

## network subnet rename

Rename a layer 3 subnet

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Rename a Subnet.

## Parameters

### -ipSPACE <IPspace> - IPspace Name

The IPspace to which the subnet belongs.

**-subnet-name <subnet name> - Subnet Name**

The name of the subnet to rename.

**-new-name <text> - New Name**

The new name for the subnet.

## Examples

The following example renames subnet **s1** to **s3**.

```
cluster1::> network subnet rename -ipSpace Default -subnet s1 -new-name s3
```

# network subnet show

Display subnet information

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

Display subnet information.

## Parameters

{[-fields <fieldname>,...]}

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance ]}

If you specify the **-instance** parameter, the command displays detailed information about all fields.

[-ipSpace <IPspace>] - IPspace Name

Selects the subnets that match the given IPspace name.

[-subnet-name <subnet name>] - Subnet Name

Selects the subnets that match the given subnet name.

[-broadcast-domain <Broadcast Domain>] - Broadcast Domain

Selects the subnets that match the given broadcast domain name.

[-subnet <IP Address/Mask>] - Layer 3 Subnet

Selects the subnets that match the given address and mask.

**[-gateway <IP Address>] - Gateway**

Selects the subnets that match the given gateway address.

**[-ip-ranges {<ipaddr>|<ipaddr>-<ipaddr>}] - IP Addresses or IP Address Ranges**

Selects the subnets that match the given IP range.

**[-total-count <integer>] - Total Address Count**

Selects the subnets that match the given total address count.

**[-used-count <integer>] - Used Address Count**

Selects the subnets that match the given number of addresses allocated.

**[-available-count <integer>] - Available Address Count**

Selects the subnets that match the given number of addresses available.

## Examples

The following example displays general information about the subnets.

```
cluster1::> network subnet show
IPspace: Default
  Subnet
  Name      Subnet          Broadcast
  Domain    Gateway         Avail/
  Total    Ranges
-----
s4         192.168.4.0/24  bd4           192.168.4.1   5/5   192.168.5.6-
192.168.5.10
s6         192.168.6.0/24  bd4           192.168.6.1   5/5   192.168.6.6-
192.168.6.10
IPspace: ips1
  Subnet
  Name      Subnet          Broadcast
  Domain    Gateway         Avail/
  Total    Ranges
-----
s10        192.168.6.0/24  bd10          192.168.6.1   0/0   -
3 entries were displayed.
```

## network test-link run-test

Test link bandwidth

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `network test-link run-test` command runs a performance test between two nodes. The command requires a source node, Vserver, and destination address.

Before executing the **network test-link run-test** command, the [network test-link start-server](#) command must be run to start a server on the node hosting the destination LIF. After all tests to that node are complete the [network test-link stop-server](#) command must be run to stop the server.

The test results are stored non-persistently and can be viewed using the [network test-link show](#) command. Results include input parameters, the bandwidth achieved, and the date and time of the test.

## Parameters

### **-node {<nodename>|local} - Node Name**

Use this parameter to specify the node which initiates the test.

### **-vserver <vserver> - Vserver**

Use this parameter to specify the Vserver to access the destination LIF. DC (Data Channel) Vserver option is available only in an ONTAP Select or ONTAP Cloud cluster. It is a special vserver that hosts LIFs that are used to mirror data aggregates to partner node.

### **-destination <Remote InetAddress> - Destination**

Use this parameter to specify the destination IP address.

## Examples

The following example runs a test between the cluster LIFs, including the start and stop of the server side of the test:

```
cluster1::*> network test-link start-server -node node1

cluster1::*> network test-link run-test -node node2 -vserver Cluster -destination
172.31.112.173
Node: node2
  Vserver: Cluster
  Destination: 172.31.112.173
Time of Test: 4/22/2016 15:33:18
  MB/s: 41.2678

cluster1::*> network test-link stop-server -node node1
cluster1::*> network test-link show
```

Node	Vserver	Destination	Time of Test	MB/s
node2	Cluster	172.31.112.173	4/22/2016 15:33:18	41.2678

- [network test-link stop-server](#)
- [network test-link show](#)

# network test-link show

Display test results

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `network test-link show` command displays the results of prior [network test-link run-test](#) commands.

The test results are stored non-persistently and can be viewed using the `network test-link show` command. Results include input parameters, the bandwidth achieved, and the date and time of the test.

## Parameters

`{ [-fields <fieldname>, ... ] }`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

`[ [-instance ] ] }`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`-node {<nodename>|local} - Node`

Selects the nodes that match this parameter value. Use this parameter to display the test results specific to a node. By default, the test results across all nodes are shown.

`-vserver <vserver> - Vserver`

Use this parameter to display the test results specific to a Vserver. Use DC (Data Channel) Vserver option only in an ONTAP Select or ONTAP Cloud cluster to show network performance of links hosting DC LIFs. DC Vserver is a special Vserver that hosts LIFs that are used to mirror data aggregates to partner node

`[-destination <Remote InetAddress>] - Destination`

Use this parameter to display the test results associated with the specified destination.

**[-timestamp <MM/DD/YYYY HH:MM:SS>] - Time of Test**

Use this parameter to display the test results with the specified timestamp.

**[-bandwidth <double>] - MB/s**

Use this parameter to display the test results only matching the specified bandwidth.

## Examples

The following example runs a test between the cluster LIFs twice and then demonstrates the show command results:

```
cluster1::*> network test-link run-test -node node2 -vserver Cluster -destination
172.31.112.173
Node: node2
  Vserver: Cluster
  Destination: 172.31.112.173
  Time of Test: 4/25/2016 10:37:52
  MB/s: 29.9946
cluster1::*> network test-link run-test -node node2 -vserver Cluster -destination
172.31.112.173
Node: node2
  Vserver: Cluster
  Destination: 172.31.112.173
  Time of Test: 4/25/2016 10:38:32
  MB/s: 39.8192
cluster1::network test-link*> show
Node          Vserver      Destination  Time of Test  MB/s
-----
node2        Cluster      172.31.112.173  4/25/2016 10:38:32
39.8192
```

## Related Links

- [network test-link run-test](#)

# network test-link start-server

Start server for bandwidth test

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **network test-link start-server** command starts the server side of the **network test-link** test on the designated node.

Only one server at a time can be running for the **network test-link** command on a given node. If the **network test-link start-server** command is issued and a server is already running on the node, then the command is ignored, and the existing server continues to run.

The server started is listening on port 5201.

## Parameters

**-node {<nodename>|local} - Node Name**

Use this parameter to specify the node where the server is to be started.

## Examples

The following example starts a server:

```
cluster1::*> network test-link start-server -node node1
```

## network test-link stop-server

Stop server for bandwidth test

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **network test-link stop-server** command stops the **network test-link** server running on the designated node.

## Parameters

**-node {<nodename>|local} - Node Name**

Use this parameter to specify the node where the server is to be stopped.

## Examples

The following example starts a server and stops it:

```
cluster1::*> network test-link start-server -node node1  
  
cluster1::*> network test-link stop-server -node node1
```

# network tuning icmp modify

Modify ICMP tuning options

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command displays options which can be used to fine tune icmp protocol behavior.

## Parameters

**-node {<nodename>|local} - Node**

Sets this parameter to indicate on which node the ICMP tuning options are modified.

**[-is-drop-redirect-enabled {true|false}] - Drop redirect ICMP**

Sets this parameter to drop redirect ICMP message.

**[-tx-icmp-limit <integer>] - Maximum number of ICMP packets sent per second**

Sets the maximum number of ICMP messages including TCP RSTs can be sent per second.

**[-redirect-timeout <integer>] - Maximum seconds for route redirect timeout**

Sets this parameter to indicate the number of seconds after which the route is deleted. Value of zero means infinity. The default value is 300 seconds.

## Examples

```
cluster1::> network tuning icmp modify -node node1 -is-drop-redirect-enabled false
```

# network tuning icmp show

Show ICMP tuning options

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command displays the current state of the ICMP tuning options for the given node.

## Parameters

**{[-fields <fieldname>,...]}**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the

specified field or fields. You can use '-fields ?' to display the fields to specify.

### **[ -instance ] }**

Displays all ICMP tuning options.

### **[ -node {<nodename>|local} ] - Node**

Specifies the node for which the ICMP tuning options are displayed.

### **[ -is-drop-redirect-enabled {true|false} ] - Drop redirect ICMP**

Displays all entries that match the "is-drop-redirect-enabled" value.

### **[ -tx-icmp-limit <integer> ] - Maximum number of ICMP packets sent per second**

Displays all entries that match the "tx-icmp-limit" value.

### **[ -redirect-timeout <integer> ] - Maximum seconds for route redirect timeout**

Displays all the entries that match the "redirect-timeout" value.

## Examples

```
cluster1::> network tuning icmp show
Drop Redirect Maximum ICMP      Redirect Timeout
Node      ICMP      Sends per Second  in Seconds
-----
node1
           true      100              300
```

## network tuning icmp6 modify

Modify ICMPv6 tuning options

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command displays options which can be used to fine tune icmpv6 protocol behavior.

## Parameters

### **-node {<nodename>|local} - Node**

Sets this parameter to indicate on which node the ICMPv6 tuning options are modified.

### **[ -is-v6-redirect-accepted {true|false} ] - Accept redirects via ICMPv6**

Sets this parameter to indicate whether or not redirect ICMPv6 messages are accepted.

**[-redirect-v6-timeout <integer>] - Maximum seconds for route redirect timeout**

Sets this parameter to indicate the number of seconds after which the route is deleted. Value of zero means infinity. The default value is 300 seconds.

**[-tx-icmp6-err-limit <integer>] - Maximum number of ICMPv6 error messages sent per second**

Sets the maximum number of ICMPv6 error messages that can be sent per second.

## Examples

```
cluster1::> network tuning icmp6 modify -node node1 -is-v6-redirect-accepted false
```

# network tuning icmp6 show

Show ICMPv6 tuning options

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command displays the current state of the ICMPv6 tuning options for the given node.

## Parameters

{ [-fields <fieldname>, ... ] }

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[ [-instance ] ] }

Displays all ICMPv6 tuning options.

**[-node {<nodename>|local}] - Node**

Specifies the node for which the ICMPv6 tuning options are displayed.

**[-is-v6-redirect-accepted {true|false}] - Accept redirects via ICMPv6**

Displays all entries that match the "is-v6-redirect-accepted" value.

**[-redirect-v6-timeout <integer>] - Maximum seconds for route redirect timeout**

Displays all the entries that match the "redirect-v6-timeout" value.

**[-tx-icmp6-err-limit <integer>] - Maximum number of ICMPv6 error messages sent per second**

Displays all entries that match the "tx-icmp6-err-limit" value.

## Examples

```
cluster1::> network tuning icmp6 show
Accept Redirect Maximum ICMPv6 Error Redirect Timeout
Node      ICMPv6          Sends per Second    in Seconds
-----
node1
          true           100                 300
```

## network tuning tcp modify

Modify TCP tuning options

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

This commands sets TCP tuning options on the node.

### Parameters

**-node {<nodename>|local}** - Node

Indicates on which node the TCP tuning options will be modified.

**[-is-path-mtu-discovery-enabled {true|false}]** - Path MTU discovery enabled

Enables path MTU discovery feature.

**[-is-rfc3465-enabled {true|false}]** - RFC3465 enabled

Enables the rfc3465 feature.

**[-max-cwnd-increment <integer>]** - Maximum congestion window segments incrementation

Sets the maximum congestion window increment segments during slow start.

**[-is-rfc3390-enabled {true|false}]** - RFC3390 enabled

Enables the rfc3390 feature.

**[-is-sack-enabled {true|false}]** - SACK support enabled

Enables the selective ACK feature.

## Examples

```
cluster1::> network tuning tcp modify -node node1 -is-path-mtu-discovery-enabled false
```

# network tuning tcp show

Show TCP tuning options

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command displays the current state of the TCP tuning options for the given node.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ -instance ] }**

Displays all TCP tuning options.

**[-node {<nodename>|local}] - Node**

Specifies the node for which the TCP tuning options will be displayed.

**[-is-path-mtu-discovery-enabled {true|false}] - Path MTU discovery enabled**

Displays all entries that match the "is-path-mtu-discovery-enabled" value.

**[-is-rfc3465-enabled {true|false}] - RFC3465 enabled**

Displays all entries that match the "is-rfc3465-enabled" value.

**[-max-cwnd-increment <integer>] - Maximum congestion window segments incrementation**

Displays all entries that match the "max-cwnd-increment" value.

**[-is-rfc3390-enabled {true|false}] - RFC3390 enabled**

Displays all entries that match the "is-rfc3390-enabled" value.

**[-is-sack-enabled {true|false}] - SACK support enabled**

Displays all entries that match the "is-sack-enabled" value.

## Examples

```
cluster1::> network tuning tcp show
      Path MTU          Maximum          Selective
Node   Discovery  RFC3465 Congestion Window RFC3390 Ack
      Enabled    Enabled Incrementation   Enabled Enabled
-----
node1
```

true	true	2	true	true
------	------	---	------	------

## pod status show

Get the pod status.

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `pod status show` command displays the current status of the pod.

## Examples

The following example displays the pod status show:

```
cluster1::> pod status show
uuid                               name          status
-----
1cd8a442-86d1-11e0-ae1c-123478563412 pod1          running

1 entries was displayed.

cluster1::>
```

## protection-type show

Display the supported protection types and available RPOs

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

This command displays the protection types available for application provisioning.

## Parameters

{ [-fields <fieldname>, ...]

Specifies fields that you want included in the output. You can use `-fields ?` to display the available fields.

**[`-instance`] }**

Specifies the display of all available fields for each selected protection type.

**[`-vserver <vserver name>`] - Vserver**

Selects the protection types of Vservers that match the parameter value.

**[`-protection-type {local|remote}`] - Protection Type**

Selects the protection types that match the parameter value.

**[`-rpo-list <text>,...`] - List of available RPOs**

Selects the protection types whose list of available RPOs matches the parameter value.

**[`-rpo-list-description <text>,...`] - List of descriptions of available RPOs**

Selects the protection types whose list of description of available RPOs matches the parameter value.

**[`-description <text>`] - Description of Protection Type**

Selects the protection types with a description that matches the parameter value.

## Examples

The following example displays the protection types and the associated available RPOs for all Vservers in the cluster.

```
cluster1::*> protection-type show
Vserver Protection Type RPO List
-----
vs1
    local          hourly, none
    remote         none
vs2
    local          hourly, none
    remote         none, zero
```

# qos adaptive-policy-group create

Create an adaptive policy group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **qos adaptive-policy-group create** command creates a new adaptive policy group. After the adaptive policy group is created, you can assign one or more storage objects to the policy. When a storage object is assigned to an adaptive policy group, the maximum throughput QoS setting

automatically adjusts based on the storage object used space or the storage object allocated space. QoS minimum throughput setting is calculated from the expected-iops parameter and the storage object allocated size. It is set only for the storage objects that reside on AFF platforms.

After you create an adaptive policy group, use the storage object create command or storage object modify command to apply the adaptive policy group to a storage object.

## Parameters

### **-policy-group <text> - Name**

Specifies the name of the adaptive policy group. Adaptive policy group names must be unique and are restricted to 127 alphanumeric characters including underscores "\_" and hyphens "-". Adaptive policy group names must start with an alphanumeric character. Use the [qos adaptive-policy-group rename](#) command to change the adaptive policy group name.

### **-vserver <vserver name> - Vserver**

Specifies the data Vserver to which this adaptive policy group belongs to. You can apply this adaptive policy group to only the storage objects contained in the specified Vserver. If the system has only one Vserver, then the command uses that Vserver by default.

### **-expected-iops {<integer>[IOPS[/{GB|TB}]] (default: TB)} - Expected IOPS**

Specifies the minimum expected IOPS per TB or GB allocated based on the storage object allocated size.

### **-peak-iops {<integer>[IOPS[/{GB|TB}]] (default: TB)} - Peak IOPS**

Specifies the maximum possible IOPS per TB or GB allocated based on the storage object allocated size or the storage object used size.

### **[-absolute-min-iops <qos\_tput>] - Absolute Minimum IOPS**

Specifies the absolute minimum IOPS which is used as an override when the expected IOPS is less than this value. The default value is computed as follows:

if expected-iops  $\geq$  6144/TB, then absolute-min-iops = 1000IOPS; if expected-iops  $\geq$  2048/TB and expected-iops  $<$  6144/TB, then absolute-min-iops = 500IOPS; if expected-iops  $\geq$  1/MB and expected-iops  $<$  2048/TB, then absolute-min-iops = 75IOPS.

### **[-expected-iops-allocation {used-space|allocated-space}] - Expected IOPS Allocation**

Specifies the expected IOPS allocation policy. The allocation policy is either **allocated-space** or **used-space**. When the expected-iops-allocation policy is set to **allocated-space**, the expected IOPS is calculated based on the size of the storage object. When the expected-iops-allocation policy is set to **used-space**, the expected IOPS is calculated based on the amount of data stored in the storage object taking into account storage efficiencies. The default value is **allocated-space**.

### **[-peak-iops-allocation {used-space|allocated-space}] - Peak IOPS Allocation**

Specifies the peak IOPS allocation policy. The allocation policy is either **allocated-space** or **used-space**. When the peak-iops-allocation policy is set to **allocated-space**, the peak IOPS is calculated based on the size of the storage object. When the peak-iops-allocation policy is set to **used-space**,

the peak IOPS is calculated based on the amount of data stored in the storage object taking into account storage efficiencies. The default value is **used-space** .

### **[-block-size {ANY|4K|8K|16K|32K|64K|128K}] - Block Size**

Specifies the I/O block size for the QoS adaptive policy group. The default value is "ANY". When block-size of "ANY" is specified, then control is by IOPS. When block-size other than "ANY" is specified, then control is by IOPS and bytes per second(bps). bps is the product of IOPS and block-size.

## Examples

```
cluster1::> qos adaptive-policy-group create p1 -vserver vs1
           -expected-iops 100IOPS/TB -peak-iops 1000/TB
```

Creates the "p1" adaptive policy group which belongs to Vserver "vs1" with expected-iops of 100IOPS/TB and peak-iops of 1000IOPS/TB with default value for absolute-min-iops

```
cluster1::> qos adaptive-policy-group create p2 -vserver vs1
           -expected-iops 100IOPS/GB -peak-iops 1000IOPS/GB
           -absolute-min-iops 200IOPS
```

Creates the "p1" adaptive policy group which belongs to Vserver "vs1" with expected-iops of 100IOPS/TB and peak-iops of 1000IOPS/TB with the absolute-min-iops set to 200IOPS.

## Related Links

- [qos adaptive-policy-group rename](#)

# qos adaptive-policy-group delete

Delete an adaptive policy group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **qos adaptive-policy-group delete** command deletes an adaptive policy group from a cluster. You cannot delete a policy group if a QoS workload associated with a storage object is assigned to it unless you use the **-force** parameter. Using the **-force** parameter will delete all the QoS workloads for storage objects associated with the specified adaptive policy groups .

Only user created adaptive policy groups can be deleted. Default adaptive policy groups are read only and cannot be deleted.

## Parameters

### **-policy-group <text> - Name**

Specifies the name of the adaptive policy group that you want to delete.

### **[-force <>true>] - Force Delete Workloads for the QoS adaptive policy group**

Specifies whether to delete an adaptive policy group along with any underlying workloads.

## Examples

The following example deletes "p1" adaptive policy group:

```
cluster1::> qos adaptive-policy-group delete p1
```

Deletes the "p1" adaptive policy group along with any underlying QoS workloads.

```
cluster1::> qos adaptive-policy-group delete p1 -force
```

# qos adaptive-policy-group modify

Modify an adaptive policy group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **qos adaptive-policy-group modify** command modifies an adaptive policy group.

Only user-created adaptive policy groups can be modified. Default adaptive policy groups are read-only and cannot be modified.

## Parameters

### **-policy-group <text> - Name**

Specifies the name of the adaptive policy group. Adaptive policy group names must be unique and are restricted to 127 alphanumeric characters including underscores "\_" and hyphens "-". Adaptive policy group names must start with an alphanumeric character. Use the [qos adaptive-policy-group rename](#) command to change the adaptive policy group name.

### **[-expected-iops {<integer>[IOPS[/{GB|TB}]] (default: TB)}] - Expected IOPS**

Specifies the minimum expected IOPS per TB or GB allocated based on the storage object allocated size. QoS minimum throughput setting is calculated from the expected-iops parameter.

It is set only for the storage objects that reside on AFF platforms.

### **[-peak-iops {<integer>[IOPS[/{GB|TB}]] (default: TB)}] - Peak IOPS**

Specifies the maximum possible IOPS per TB or GB allocated based on the storage object allocated size or the storage object used size.

### **[-absolute-min-iops <qos\_tput>] - Absolute Minimum IOPS**

Specifies the absolute minimum IOPS which is used as an override when the expected IOPS is less than this value. The default value is computed as follows:

if expected-iops  $\geq$  6144/TB, then absolute-min-iops = 1000IOPS; if expected-iops  $\geq$  2048/TB and expected-iops  $<$  6144/TB, then absolute-min-iops = 500IOPS; if expected-iops  $\geq$  1/MB and expected-iops  $<$  2048/TB, then absolute-min-iops = 75IOPS.

### **[-expected-iops-allocation {used-space|allocated-space}] - Expected IOPS Allocation**

Specifies the expected IOPS allocation policy. The allocation policy is either **allocated-space** or **used-space**. When the expected-iops-allocation policy is set to **allocated-space**, the expected IOPS is calculated based on the size of the storage object. When the expected-iops-allocation policy is set to **used-space**, the expected IOPS is calculated based on the amount of data stored in the storage object taking into account storage efficiencies. The default value is **allocated-space**.

### **[-peak-iops-allocation {used-space|allocated-space}] - Peak IOPS Allocation**

Specifies the peak IOPS allocation policy. The allocation policy is either **allocated-space** or **used-space**. When the peak-iops-allocation policy is set to **allocated-space**, the peak IOPS is calculated based on the size of the storage object. When the peak-iops-allocation policy is set to **used-space**, the peak IOPS is calculated based on the amount of data stored in the storage object taking into account storage efficiencies. The default value is **used-space**.

### **[-block-size {ANY|4K|8K|16K|32K|64K|128K}] - Block Size**

Specifies the I/O block size for the QoS adaptive policy group. The default value is "ANY". When block-size of "ANY" is specified, then control is by IOPS. When block-size other than "ANY" is specified, then control is by IOPS and bytes per second(bps). bps is the product of IOPS and block-size.

## Examples

The following example modifies the "p1" adaptive policy group with specified values.

```
cluster1::> qos adaptive-policy-group modify -policy-group p1
           -expected-iops 200IOPS/TB -peak-iops 2000IOPS/TB
           -absolute-min-iops 100IOPS
```

## Related Links

- [qos adaptive-policy-group rename](#)

# qos adaptive-policy-group rename

Rename an adaptive policy group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `qos adaptive-policy-group rename` command changes the name of an existing adaptive policy group.

## Parameters

**-policy-group <text> - Name**

Specifies the existing name of the adaptive policy group that you want to rename.

**-new-name <text> - New adaptive policy group name**

Specifies the new name of the adaptive policy group. Adaptive policy group names must be unique and are restricted to 127 alphanumeric characters including underscores "\_" and hyphens "-". Adaptive policy group names must start with an alphanumeric character.

## Examples

```
cluster1::> qos adaptive-policy-group rename -policy-group p1 -new-name p1_new
```

Renames the adaptive policy group from "p1" to "p1\_new".

# qos adaptive-policy-group show

Display a list of adaptive policy groups

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `qos adaptive-policy-group show` command shows the current settings of the adaptive policy groups on a cluster. You can view the list of adaptive policy groups and also the detailed information about a specific adaptive policy group.

## Parameters

**{ [-fields <fieldname>, ...]**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the

specified field or fields. You can use '-fields ?' to display the fields to specify.

### **[`-instance`] }**

If you specify the `-instance` parameter, the command displays detailed information about all fields.

### **[`-policy-group <text>`] - Name**

Selects the adaptive policy groups that match this parameter value.

Adaptive policy groups define measurable service level objectives (SLOs) that adjust based on the storage object used space or the storage object allocated space.

### **[`-vserver <vserver name>`] - Vserver**

If this parameter is specified, the command displays information only about the adaptive policy groups with a matching vserver.

### **[`-uuid <UUID>`] - Uuid**

If this parameter is specified, the command displays information only about the adaptive policy groups with the specified UUID.

### **[`-pgid <integer>`] - ID**

If this parameter is specified, the command displays information only about the adaptive policy groups that match the given policy group ID, which is an integer that uniquely identifies the adaptive policy group.

### **[`-expected-iops {<integer>[IOPS[/{GB|TB}]] (default: TB)}`] - Expected IOPS**

If this parameter is specified, the command displays information only about the adaptive policy groups with the specified minimum expected IOPS per TB or GB.

### **[`-peak-iops {<integer>[IOPS[/{GB|TB}]] (default: TB)}`] - Peak IOPS**

If this parameter is specified, the command displays information only about the adaptive policy groups with the specified maximum possible IOPS per TB or GB.

### **[`-absolute-min-iops <qos_tput>`] - Absolute Minimum IOPS**

If this parameter is specified, the command displays information only about the adaptive policy groups with the specified absolute minimum IOPS.

### **[`-expected-iops-allocation {used-space|allocated-space}`] - Expected IOPS Allocation**

If this parameter is specified, the command displays information only about the adaptive policy groups with the specified expected IOPS allocation policy used to compute the expected IOPS per TB or GB.

### **[`-peak-iops-allocation {used-space|allocated-space}`] - Peak IOPS Allocation**

If this parameter is specified, the command displays information only about the adaptive policy groups with the specified peak IOPS allocation policy used to compute the maximum possible IOPS per TB or GB.

**[-block-size {ANY|4K|8K|16K|32K|64K|128K}] - Block Size**

Specifies the I/O block size for the QoS adaptive policy group. The default value is "ANY". When block-size of "ANY" is specified, then control is by IOPS. When block-size other than "ANY" is specified, then control is by IOPS and bytes per second(bps). bps is the product of IOPS and block-size.

**[-num-workloads <integer>] - Number of Workloads**

If this parameter is specified, the command displays information only about the adaptive policy groups with the specified number of workloads.

## Examples

The example above displays all adaptive policy groups on the cluster.

```
cluster1::> qos adaptive-policy-group show
qos adaptive-policy-group show
Expected   Peak      Minimum   Block
Name       Vserver  Wklds    IOPS      IOPS      IOPS      Size
-----
apg1       vs1      1        100IOPS/MB 1000IOPS/MB 75IOPS    8K
apg2       vs1      1        100IOPS/MB 1000IOPS/MB 75IOPS    4K
extreme    clus-1  0        6144IOPS/TB 12288IOPS/TB 1000IOPS  ANY
performance clus-1  0        2048IOPS/TB 4096IOPS/TB 500IOPS  ANY
value      clus-1  0        128IOPS/TB 512IOPS/TB 75IOPS    ANY
5 entries were displayed.
```

## qos policy-group create

Create a policy group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **qos policy-group create** command creates a new policy group. You can use a QoS policy group to control a set of storage objects known as "workloads" - LUNs, volumes, files, or Vservers. Policy groups define measurable service level objectives (SLOs) that apply to the storage objects with which the policy group is associated.

After you create a policy group, you use the storage object create command or the storage object modify command to apply the policy group to a storage object.

### Parameters

**-policy-group <text> - Policy Group Name**

Specifies the name of the policy group. Policy group names must be unique and are restricted to 127 alphanumeric characters including underscores "\_" and hyphens "-". Policy group names must start with an alphanumeric character. You use the [qos policy-group rename](#) command to change the policy group name.

**-vserver <vserver name> - Vserver**

Specifies the data Vserver to which this policy group belongs. You can apply this policy group to only the storage objects contained in the specified Vserver. For example, if you want to apply this policy group to a volume, that volume must belong to the specified Vserver. Using this parameter does not apply the policy group's SLOs to the Vserver. You need to use the `vserver modify` command if you want to apply this policy group to the Vserver. If the system has only one Vserver, then the command uses that Vserver by default.

**[-max-throughput <qos\_tput>] - Maximum Throughput**

Specifies the maximum throughput for the policy group. A maximum throughput limit specifies the throughput that the policy group must not exceed. It is specified in terms of IOPS or MB/s, or a combination of comma separated IOPS and MB/s. The range is one to infinity. A value of zero is accepted but is internally treated as infinity.

The values entered here are case-insensitive, and the units are base ten. There should be no space between the number and the units. The default value for max-throughput is infinity, which can be specified by the special value "INF". Note that there is no default unit - all numbers except zero require explicit specification of the units.

Two reserved keywords, "none" and "INF", are available for the situation that requires removal of a value, and the situation that needs to specify the maximum available value.

Examples of valid throughput specifications are: "100B/s", "10KB/s", "1gb/s", "500MB/s", "1tb/s", "100iops", "100iops,400KB/s", and "800KB/s,100iops"

**[-min-throughput <qos\_tput>] - Minimum Throughput**

Specifies the minimum throughput for the policy group. A minimum throughput specifies the desired performance level for a policy group. It is specified in terms of IOPS or MB/s, or a combination of comma separated IOPS and MB/s.

The values entered here are case-insensitive, and the units are base ten. There should be no space between the number and the units. The default value for min-throughput is "0". The default unit is IOPS.

One reserved keyword, 'none' is available for the situation that requires removal of a value.

Examples of valid throughput specifications are: "100B/s", "10KB/s", "1gb/s", "500MB/s", "1tb/s", "100iops", "100iops,400KB/s", and "800KB/s,100iops"

**[-is-shared {true|false}] - Is Shared**

Specifies whether the policy group can be shared or not. The default value is "true". This parameter specifies if the SLOs of the policy group are shared between the workloads or if the

SLOs are applied separately to each workload.

## Examples

```
cluster1::> qos policy-group create p1 -vserver vs1
```

Creates the "p1" policy group which belongs to Vserver "vs1" with default policy values.

```
cluster1::> qos policy-group create p2 -vserver vs1 -max-throughput 500MB/s
```

Creates the "p2" policy group which belongs to Vserver "vs1" with the maximum throughput set to 500 MB/s.

```
cluster1::> qos policy-group create p3 -vserver vs1 -max-throughput 500MB/s -is-shared false
```

Creates the "p3" policy group which belongs to Vserver "vs1" with the maximum throughput set to 500 MB/s and shared set to false.

## Related Links

- [qos policy-group rename](#)

# qos policy-group delete

Delete an existing QoS Policy Group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **qos policy-group delete** command deletes a policy group from a cluster. You cannot delete a policy group if a qos workload associated with storage object is assigned to it unless you use "-force". Using "-force" will delete all the qos workloads for storage objects associated with the specified policy groups .

You can only delete user-defined policy groups. You cannot delete preset policy groups.

## Parameters

**-policy-group <text> - Policy Group Name**

Specifies the name of the policy group that you want to delete.

**[-force <true>] - Force Delete Workloads for the QoS Policy Group**

Specifies whether to delete a policy group along with any underlying workloads.

## Examples

```
cluster1::> qos policy-group delete p1
```

Deletes the "p1" policy group.

```
cluster1::> qos policy-group delete p1 -force
```

Deletes the "p1" policy group along with any underlying qos workloads.

# qos policy-group modify

Modify a policy group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `qos policy-group modify` command modifies a user-created policy group.

## Parameters

**-policy-group <text> - Policy Group Name**

Specifies the name of the policy group that you want to modify.

**[-max-throughput <qos\_tput>] - Maximum Throughput**

Specifies the maximum throughput for the policy group. A maximum throughput limit specifies the throughput that the policy group must not exceed. It is specified in terms of IOPS or MB/s, or a combination of comma separated IOPS and MB/s. The range is one to infinity. A value of zero is accepted but is internally treated as infinity.

The values entered here are case-insensitive, and the units are base ten. There should be no space between the number and the units. The default value for max-throughput is infinity, which can be specified by the special value "INF". Note there is no default unit - all numbers except zero require explicit specification of the units.

Two reserved keywords, "none" and "INF", are available for the situation that requires removal of a value, and the situation that needs to specify the maximum available value.

Examples of valid throughput specifications are: "100B/s", "10KB/s", "1gb/s", "500MB/s", "1tb/s", and "100iops".

### **[-min-throughput <qos\_tput>] - Minimum Throughput**

Specifies the minimum throughput for the policy group. A minimum throughput specifies the desired performance level for a policy group. It is specified in terms of IOPS or MB/s, or a combination of comma separated IOPS and MB/s.

The values entered here are case-insensitive, and the units are base ten. There should be no space between the number and the units. The default value for min-throughput is "0". The default unit is IOPS.

One reserved keyword, 'none' is available for the situation that requires removal of a value.

Examples of valid throughput specifications are: "100B/s", "10KB/s", "1gb/s", "500MB/s", "1tb/s", "100iops", "100iops,400KB/s", and "800KB/s,100iops"

## Examples

```
cluster1::> qos policy-group modify p1 -max-throughput 10IOPS
```

Modifies the "p1" policy group and sets its max throughput value to 10 IOPS.

## qos policy-group rename

Rename a policy group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `qos policy-group rename` command changes the name of an existing policy group.

## Parameters

**-policy-group <text> - Policy Group Name**

Specifies the existing name of the policy group that you want to rename.

**-new-name <text> - New Policy Group Name**

Specifies the new name of the policy group. Policy group names must be unique and are restricted to 127 alphanumeric characters including underscores "\_" and hyphens "-". Policy group names must start with an alphanumeric character.

## Examples

```
cluster1::> qos policy-group rename -policy-group p1 -new-name p1_new
```

Renames the policy group from "p1" to "p1\_new".

# qos policy-group show

Display a list of policy groups

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **qos policy-group show** command shows the current settings of the policy groups on a cluster. You can display a list of the policy groups and you can view detailed information about a specific policy group.

## Parameters

{ [-fields <fieldname>, ...]

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[-instance ]}

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-policy-group <text>] - Policy Group Name**

Selects the policy groups that match this parameter value

Policy groups define measurable service level objectives (SLOs) that apply to the storage objects with which the policy group is associated.

**[-vserver <vserver name>] - Vserver**

Selects the policy groups that match this parameter value

**[-uuid <UUID>] - Uuid**

Selects the policy groups that match this parameter value

**[-class <QoS Configuration Class>] - Policy Group Class**

Selects the policy groups that match this parameter value

**[-pgid <integer>] - Policy Group ID**

Selects the policy groups that match this parameter value

This uniquely identifies the policy group

**[-max-throughput <qos\_tput>] - Maximum Throughput**

Selects the policy groups that match this parameter value

A maximum throughput limit specifies the throughput (in IOPS or MB/s) that the policy group must not exceed.

#### **[-min-throughput <qos\_tput>] - Minimum Throughput**

Selects the policy groups that match this parameter value

A minimum throughput specifies the desired performance level for a policy group.

#### **[-num-workloads <integer>] - Number of Workloads**

Selects the policy groups that match this parameter value.

#### **[-throughput-policy <text>] - Throughput Policy**

Selects the policy groups that match this parameter value. You can specify the throughput range in terms of IOPS or data rate. For example, **0-INF**, **0-400IOPS**, **0-200KB/s**, **0-400MB/s**.

#### **[-is-shared {true|false}] - Is Shared**

Selects the policy groups that match this parameter value.

The shared value specifies whether the policy group is a shared policy group or not.

#### **[-is-auto-generated {true|false}] - Is Policy Auto Generated**

Selects the policy groups that match this parameter value.

The auto-generated value specifies whether the policy group is an automatically generated policy group or not.

## Examples

```
cluster1::> qos policy-group show
Name          Vserver      Class           Wklds Throughput
-----
pg1           vs4          user-defined 0     0-200IOPS
pg2           vs0          user-defined 0     0-500IOPS
pg5           vs0          user-defined 0     0-300IOPS
pg6           vs0          user-defined 0     0-INF
4 entries were displayed.
```

The example above displays all policy groups on the cluster.

## qos settings throughput-floors-v2

Enable/Disable throughput floors v2 on AFF

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **qos settings throughput-floors-v2** command is used to enable or disable floors v2 on AFF. The default is enabled. With floors v2 enabled, throughput floors can be met when controllers are heavily utilized at the expense of higher latency on other workloads. Floors v2 applies to both QoS and Adaptive QoS.

## Parameters

**-enable {true|false} - enable or disable throughput floors v2 on AFF**

This specifies if floors v2 is enabled or disabled. If this parameter is specified with **false** floors v2 will be disabled.

## Examples

The following example disables floors v2 on AFF.

```
cluster1::*> qos settings throughput-floors-v2 -enable false
```

# qos settings cache modify

Modify the cache policy

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **qos settings cache modify** command modifies the existing default caching-policy. The list of caching policies can be obtained from the **qos setting cache show -fields cache-setting** command.

## Parameters

**-cache-setting <text> - Cache Policy Name**

Valid inputs to this parameter include any one of the listed caching-policies. This command is to be used together with the default parameter. If you use this parameter, the command modifies the specified caching-policy based on the default parameter.

**[-default {true|false}] - Is Default?**

Valid inputs to this parameter are true and false. Together with cache-setting, this parameter helps set or unset a caching-policy as default.

## Examples

```
cluster1::> qos settings cache modify -default true -cache-setting random_read_write-  
random_write
```

Sets caching-policy random\_read\_write-random\_write as default.

## qos settings cache show

Display list of cache policies

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The ``qos settings cache show`` shows the current caching-policies, class to which they belong, the number of workloads associated with each of the policies, and whether or not they are set to default. The following external-cache policies are available:

- none - Does not cache any user data or metadata blocks.
- auto - Read caches all metadata and randomly read user data blocks, and write caches all randomly overwritten user data blocks.
- all - Read caches all data blocks read and written. It does not do any write caching.
- all-random\_write - Read caches all data blocks read and written. It also write caches randomly overwritten user data blocks.
- all\_read - Read caches all metadata, randomly read, and sequentially read user data blocks.
- all\_read-random\_write - Read caches all metadata, randomly read, and sequentially read user data blocks. It also write caches randomly overwritten user data blocks.
- all\_read\_random\_write - Read caches all metadata, randomly read, sequentially read and randomly written user data.
- all\_read\_random\_write-random\_write - Read caches all metadata, randomly read, sequentially read, and randomly written user data blocks. It also write caches randomly overwritten user data blocks.
- meta - Read caches only metadata blocks.
- meta-random\_write - Read caches all metadata and write caches randomly overwritten user data blocks.
- noread-random\_write - Write caches all randomly overwritten user data blocks. It does not do any read caching.
- random\_read - Read caches all metadata and randomly read user data blocks.
- random\_read\_write - Read caches all metadata, randomly read and randomly written user data blocks.

- `random_read_write-random_write` - Read caches all metadata, randomly read, and randomly written user data blocks. It also write caches randomly overwritten user data blocks.

Note that in a caching-policy name, a hyphen (-) separates read and write caching policies.

## Parameters

### `{ [-fields <fieldname>, ... ] }`

The input to this parameter is one of the following: {cache-setting|class|default|num-workloads}. If you use this parameter, the command displays information related to the specified input field.

### `[ [-instance ] ] }`

If you use this parameter, the command displays information about the caching-policies in a list format.

### `[-cache-setting <text>] - Cache Policy Name`

The input to this parameter is any one of the above listed caching-policies. If you use this parameter, the command displays information corresponding to the specified caching-policy.

### `[-class <QoS Configuration Class>] - Cache Policy Class`

The input to this parameter is one of the following: {undefined|preset|user-defined|system-defined|autovolume}. If you use this parameter, the command displays information corresponding to the specified policy-group class.

### `[-default {true|false}] - Is Default?`

The input to this parameter is true and false. If you use this parameter, the command displays information corresponding to entries that have the specified default value.

### `[-num-workloads <integer>] - Number Of Workloads With This Policy`

The input to this parameter is an integer. If you use this parameter, the command displays information about policy-groups matching the specified number of workloads.

## Examples

```
cluster1::> qos settings cache show
Policy Name  Class          Num Workloads  Default
-----
all          preset        0              false
all-random_write
             preset        0              false
all_read     preset        0              false
all_read-random_write
             preset        0              false
all_read_random_write
             preset        0              false
all_read_random_write-random_write
```

qos statistics characteristics show

```

    preset      0      false
auto    preset      2      false
meta    preset      0      false
meta-random_write
    preset      0      false
none    preset      0      false
noread-random_write
    preset      0      false
random_read preset    25     false
random_read_write
    preset      0      false
random_read_write-random_write
    preset      28     true
14 entries were displayed.
```

Shows QoS settings for the caching policies.

## qos statistics characteristics show

Display QoS policy group characterization

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **qos statistics characteristics show** command displays data that characterizes the behavior of QoS policy groups.

The command displays the following data:

- The QoS policy group name (Policy Group)
- Input/output operations performed per second (IOPS)
- Throughput achieved in kilobytes per second (KB/s) or megabytes per second (MB/s) as appropriate (Throughput)
- Request size in bytes (B) (Request size)
- Read percentage from total I/O (Read)
- Concurrency, which indicates the number of concurrent users generating the I/O traffic (Concurrency)

The results displayed per iteration are sorted by IOPS. Each iteration starts with a row that displays the total IOPS used across all QoS policy groups. Other columns in this row are either totals or averages.

## Parameters

### **[-node {<nodename>|local}] - Node**

Selects the policy groups that match this parameter value. If you do not specify this parameter, the command displays data for the entire cluster.

### **[-iterations <integer>] - Number of Iterations**

Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

### **{ [-rows <integer>] - Number of Rows in the Output**

Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.

### **[-policy-group <text>] - QoS Policy Group Name**

Selects the QoS policy group whose name matches the specified value. If you do not specify this parameter, the command displays data for all QoS policy groups.

### **[-adaptive-policy-group <text>] - Adaptive QoS Policy Group Name }**

Selects the QoS adaptive policy group whose name matches the specified value. If you do not specify this parameter, the command displays data for all QoS policy groups.

### **[-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration**

Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

## Examples

```
cluster1::> qos statistics characteristics show -iterations 100 -rows 4
Policy Group          IOPS      Throughput Request size  Read Concurrency
-----
-total-              31      304.00KB/s      10041B      0%          16
_System-Best-Effort  15           0KB/s           0B          0%           0
vol1                 11      44.00KB/s       4096B       0%          40
vol2                 4       256.00KB/s      65536B      0%          14
vs1vol0              1         4.00KB/s       4096B       0%           4
-total-              37      808.00KB/s      22361B      2%           3
_System-Best-Effort  15           0KB/s           0B          0%           0
vol2                 12      768.00KB/s      65536B      0%           9
vs1vol0              8       32.00KB/s       4096B      12%           1
vol1                 2         8.00KB/s       4096B       0%           1
```

The example above displays the characteristics of the **4** QoS policy groups with the highest IOPS values and refreshes the display **100** times before terminating.

```
cluster1::> qos statistics characteristics show -iterations 100 -policy-group pg1
```

Policy Group	IOPS	Throughput	Request size	Read	Concurrency
-total-	293	3.02MB/s	10783B	54%	0
pg1	118	470.67KB/s	4096B	100%	0
-total-	181	478.14KB/s	2700B	65%	0
pg1	117	469.33KB/s	4096B	100%	0
-total-	226	525.78KB/s	2382B	60%	1
pg1	110	440.00KB/s	4096B	100%	1
-total-	233	1.67MB/s	7527B	49%	1
pg1	112	446.67KB/s	4096B	100%	1

The example above displays the system characteristics of the QoS policy group **pg1** and refreshes the display **100** times before terminating.

## qos statistics latency show

Display latency breakdown data per QoS policy group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **qos statistics latency show** command displays the average latencies for QoS policy groups across the various Data ONTAP subsystems.

The command displays the following data:

- The QoS policy group name (Policy Group)
- Total latency observed per I/O operation (Latency)
- Latency observed per I/O operation in the Network subsystem (Network)
- Latency observed per I/O operation across the internally connected nodes in a Cluster (Cluster)
- Latency observed per I/O operation in the Data management subsystem (Data)
- Latency observed per I/O operation in the Storage subsystem (Disk)
- Latency observed per I/O operation for QoS Policy Group Ceiling (QoS Max)
- Latency observed per I/O operation for QoS Policy Group Floor (QoS Min)
- Latency observed per I/O operation for NVRAM transfer (NVRAM)
- Latency observed per I/O operation for Object Store (Cloud) operations
- Latency observed per I/O operation for FlexCache (FlexCache) operations
- Latency observed per I/O operation for Synchronous Snapmirror (SM Sync) operations
- Latency observed per I/O operation for Volume Activation (VA) operations

The results displayed per iteration are sorted by the Latency field. Each iteration starts with a row that displays the average latency, in microseconds (us) or milliseconds (ms), observed across all QoS

policy groups.

## Parameters

### **[-node {<nodename>|local}] - Node**

Selects the policy groups that match this parameter value. If you do not specify this parameter, the command displays data for the entire cluster.

### **[-iterations <integer>] - Number of Iterations**

Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

### **{ [-rows <integer>] - Number of Rows in the Output**

Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.

### **[-policy-group <text>] - QoS Policy Group Name**

Selects the QoS policy group whose name matches the specified value. If you do not specify this parameter, the command displays data for all QoS policy groups.

### **[-adaptive-policy-group <text>] - Adaptive QoS Policy Group Name }**

Selects the QoS adaptive policy group whose name matches the specified value. If you do not specify this parameter, the command displays data for all QoS policy groups.

### **[-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration**

Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

## Examples

```
cluster1::> qos statistics latency show -iterations 100 -rows 3

```

The example above displays latencies for the QoS policy group **pg1** and refreshes the display **100** times before terminating.

## qos statistics performance show

Display system performance data per QoS policy group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **qos statistics performance show** command shows the current system performance levels that QoS policy groups are achieving.

The command displays the following data:

- The QoS policy group name (Policy Group)
- Input/output operations performed per second (IOPS)
- Throughput in kilobytes per second (KB/s) or megabytes per second (MB/s) as appropriate (Throughput)
- Latency observed per request in microseconds (us) or milliseconds (ms) as appropriate (Latency)

The results displayed per iteration are sorted by IOPS. Each iteration starts with a row that displays the total IOPS used across all QoS policy groups. Other columns in this row are either totals or averages.

## Parameters

### **[-node {<nodename>|local}] - Node**

Selects the policy groups that match this parameter value. If you do not specify this parameter, the command displays data for the entire cluster.

### **[-iterations <integer>] - Number of Iterations**

Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

### **{ [-rows <integer>] - Number of Rows in the Output**

Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.

### **[-policy-group <text>] - QoS Policy Group Name**

Selects the QoS policy group whose name matches the specified value. If you do not specify this parameter, the command displays data for all QoS policy groups.

### **[-adaptive-policy-group <text>] - Adaptive QoS Policy Group Name }**

Selects the QoS adaptive policy group whose name matches the specified value. If you do not specify this parameter, the command displays data for all QoS policy groups.

### **[-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration**

Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

## Examples

```
cluster1::> qos statistics performance show -iterations 100 -rows 4
Policy Group          IOPS      Throughput    Latency
-----
-total-              79      1296.00KB/s   337.41ms
_System-Best-Effort  25           0KB/s         0ms
vol1                 24       96.00KB/s    193.72ms
vol2                 18     1152.00KB/s   750.98ms
vs1vol0             12       48.00KB/s    707.38ms
-total-            109       1.99MB/s     133.27ms
_System-Best-Effort  35           0KB/s         0ms
vol2                 29       1.81MB/s     249.27ms
vs1vol0             24       96.00KB/s     48.32ms
vol1                 21       84.00KB/s    292.30ms
```

The example above displays the system performance for the **4** QoS policy groups with the highest IOPS and it refreshes the display **100** times before terminating.

```
cluster1::> qos statistics performance show -iterations 100 -policy-group pg1
Policy Group          IOPS      Throughput    Latency
-----
-total-            2833     10.66MB/s    924.00us
pg1                 2655     10.37MB/s    917.00us
-total-            2837     10.65MB/s    923.00us
pg1                 2655     10.37MB/s    917.00us
-total-            2799     10.73MB/s    802.00us
pg1                 2737     10.69MB/s    815.00us
-total-            2930     13.33MB/s    905.00us
pg1                 2720     10.62MB/s    858.00us
```

The example above displays the system performance for the QoS policy group **pg1** and refreshes the display **100** times before terminating.

## qos statistics resource cpu show

Display CPU resource utilization data per QoS policy group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `qos statistics resource cpu show` command displays the CPU utilization for QoS policy groups per node.

The command displays the following data:

- The QoS policy group name (Policy Group)
- CPU utilization observed in percentage (CPU)

The results displayed per iteration are sorted by total CPU utilization. Each iteration starts with a row that displays the total CPU utilization across all QoS policy groups.

## Parameters

### **-node {<nodename>|local} - Node**

Selects the policy groups that match this parameter value.

### **[-iterations <integer>] - Number of Iterations**

Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

### **{ [-rows <integer>] - Number of Rows in the Output**

Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.

### **[-policy-group <text>] - QoS Policy Group Name**

Selects the QoS policy group whose name matches the specified value. If you do not specify this parameter, the command displays data for all QoS policy groups.

### **[-adaptive-policy-group <text>] - Adaptive QoS Policy Group Name }**

Selects the QoS adaptive policy group whose name matches the specified value. If you do not specify this parameter, the command displays data for all QoS policy groups.

### **[-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration**

Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

## Examples

```
cluster1::> qos statistics resource cpu show -node nodeA -iterations 100 -rows 3
Policy Group          CPU
-----
-total- (100%)        9%
fast                  1%
slow                  3%
medium                5%
-total- (100%)        8%
slow                  1%
fast                  3%
medium                3%
```

The example above displays the total CPU utilization for the **3** QoS policy groups with the highest

CPU utilization and it refreshes the display **100** times before terminating.

```
cluster1::> qos statistics resource cpu show -node local -iterations 100 -policy-group
pg1
      Policy Group          CPU
-----
-total- (100%)            7%
pg1                        1%
-total- (100%)            7%
pg1                        1%
-total- (100%)            7%
pg1                        1%
-total- (100%)           10%
pg1                        1%
```

The example above displays the total CPU utilization for the QoS policy group **pg1** and refreshes the display **100** times before terminating.

## qos statistics resource disk show

Display disk resource utilization data per QoS policy group

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **qos statistics resource disk show** command displays the disk utilization for QoS policy groups per node. The disk utilization shows the percentage of time spent on the disk during read and write operations. The command displays disk utilization for system-defined policy groups; however, their disk utilization is not included in the total utilization. The command only supports hard disks.

The command displays the following data:

- The QoS policy group name (Policy Group)
- Disk utilization (Disk)
- The number of HDD data disks utilized (Number of HDD Disks)

The results displayed are sorted by total disk utilization. Each iteration starts with a row that displays the total disk utilization across all QoS policy groups.

### Parameters

**-node {<nodename>|local} - Node**

Selects the policy groups that match this parameter value.

**[ -iterations <integer> ] - Number of Iterations**

Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

**{ [ -rows <integer> ] - Number of Rows in the Output**

Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.

**[ [ -policy-group <text> ] - QoS Policy Group Name**

Selects the QoS policy group whose name matches the specified value. If you do not specify this parameter, the command displays data for all QoS policy groups.

**[ [ -adaptive-policy-group <text> ] - Adaptive QoS Policy Group Name }**

Selects the QoS adaptive policy group whose name matches the specified value. If you do not specify this parameter, the command displays data for all QoS policy groups.

**[ -refresh-display {true|false} ] - Toggle Screen Refresh Between Each Iteration**

Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

## Examples

```
cluster1::> qos statistics resource disk show -node nodeA -iterations 100 -rows 3
Policy Group          Disk Number of HDD Disks
-----
-total-              40%                27
pg1                  22%                 5
slow                 10%                10
fast                  8%                 12
_System_Default      7%                 20
-total-              42%                27
pg1                  22%                 5
slow                 12%                10
fast                  8%                 12
_System_Default      7%                 20
```

The example above displays the total disk utilization for the **3** QoS policy groups with the highest disk utilization and it refreshes the display **100** times before terminating.

```
cluster1::> qos statistics resource disk show -node local -iterations 100 -policy
-group pg1
Policy Group          Disk Number of HDD Disks
-----
-total-              3%                 10
pg1                  1%                 24
-total-              3%                 10
pg1                  1%                 24
```

-total-	3%	10
pg1	1%	24
-total-	3%	10
pg1	1%	24

The example above displays the total disk utilization for the QoS policy group **pg1** and refreshes the display **100** times before terminating.

## qos statistics volume characteristics show

Display volume characteristics

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **qos statistics volume characteristics show** command displays data that characterizes the behavior of volumes.

The command displays the following data:

- QoS volume name (Workload)
- QoS workload ID (ID)
- Input/output operations per second (IOPS)
- Throughput achieved in kilobytes per second (KB/s) or megabytes per second (MB/s) as appropriate (Throughput)
- Request size in bytes (B) (Request size)
- Read percentage from total IOPS (Read)
- Concurrency, which indicates the number of concurrent users generating the I/O traffic (Concurrency)

The results displayed per iteration are sorted by IOPS. Each iteration starts with a row that displays the total IOPS used across all volumes. Other columns in this row are either totals or averages.

### Parameters

#### **[-node {<nodename>|local}] - Node**

Selects the volumes that match this parameter value. If you do not specify this parameter, the command displays data for the entire cluster.

#### **{ [-rows <integer>] - Number of Rows in the Output**

Specifies the number of busiest QoS policy groups to display. The default setting is 10. The allowed range of values is 1 to 20.

**[-vserver <vserver name> - Vserver Name**

Specifies the Vserver to which the volume belongs.

**-volume <volume name> - Volume Name }**

Selects the characteristic data that match this parameter value. Enter a complete volume name or press the <Tab> key to complete the name. Wildcard query characters are not supported.

**[-iterations <integer>] - Number of Iterations**

Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

**[-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration**

Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

**[-show-flexgroup-as-constituents {true|false}] - Display Flexgroups as Constituents**

If the parameter is specified and if the value is true, it will display data for FlexVols and Flexgroup Constituents. Otherwise it will display data for FlexVols and Flexgroups.

## Examples

```
cluster1::> qos statistics volume characteristics show -iterations 100 -rows 3
Workload          ID      IOPS      Throughput Request size Read Concurrency
-----
-total-          -        68      176.00KB/s    2650B  7%          8
vs1vol0-wid102   102      24      96.00KB/s    4096B 20%         13
vol_1-wid103     103      20      80.00KB/s    4096B 0%          12
vol_2-wid104     104       1       0KB/s        0B    0%          0
-total-          -       157     528.00KB/s   3443B  3%          4

```

The example above displays characteristics for volume **vs0\_vol0** in Vserver **vs0** and it refreshes the display **100** times before terminating.

## qos statistics volume latency show

Display latency breakdown data per volume

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **qos statistics volume latency show** command displays the average latencies for volumes on Data ONTAP subsystems.

The command displays the following data:

- The QoS volume name (Workload)
- The QoS workload ID (ID)
- Total latency observed per I/O operation (Latency)
- Latency observed per I/O operation in the Network subsystem (Network)
- Latency observed per I/O operation across the internally connected nodes in a Cluster (Cluster)
- Latency observed per I/O operation in the Data management subsystem (Data)
- Latency observed per I/O operation in the Storage subsystem (Disk)
- Latency observed per I/O operation for QoS Policy Group Ceiling (QoS Max)
- Latency observed per I/O operation for QoS Policy Group Floor (QoS Min)
- Latency observed per I/O operation for NVRAM transfer (NVRAM)
- Latency observed per I/O operation for Object Store(Cloud) operations
- Latency observed per I/O operation for FlexCache (FlexCache) operations
- Latency observed per I/O operation for Synchronous Snapmirror (SM Sync) operations
- Latency observed per I/O operation for Volume Activation (VA) operations

The results displayed per iteration are sorted by the total latency field. Each iteration starts with a row that displays the average latency, in microseconds (us) or milliseconds (ms) observed across all volumes.

## Parameters

### **[-node {<nodename>|local}] - Node**

Selects the volumes that match this parameter value. If you do not specify this parameter, the command displays data for the entire cluster.

### **{ [-rows <integer>] - Number of Rows in the Output**

Specifies the number of busiest QoS policy groups to display. The default setting is 10. The allowed range of values is 1 to 20.

### **[-vserver <vserver name> - Vserver Name**

Specifies the Vserver to which the volume belongs.

### **-volume <volume name> - Volume Name }**

Selects the latency data that match this parameter value. Enter a complete volume name or press the <Tab> key to complete the name. Wildcard query characters are not supported.

### **[-iterations <integer>] - Number of Iterations**

Specifies the number of times that the command refreshes the display with updated data before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

### **[-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration**

Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

### **[-show-flexgroup-as-constituents {true|false}] - Display Flexgroups as Constituents**

If the parameter is specified and if the value is true, it will display data for FlexVols and Flexgroup Constituents. Otherwise it will display data for FlexVols and Flexgroups.

## Examples

```
cluster1::> qos statistics volume latency show -iterations 100 -rows 3

The example above displays latencies for volume **vs0\_vol0** in Vserver **vs0** and it refreshes the display **100** times before terminating.

# qos statistics volume performance show

Display system performance data per volume

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **qos statistics volume performance show** command shows the current system performance that each volume is achieving.

The command displays the following data:

- The QoS volume name (Workload)
- The QoS workload ID (ID)
- Input/output operations performed per second (IOPS)
- Throughput in kilobytes per second (KB/s) or megabytes per second (MB/s) as appropriate (Throughput)
- Latency observed per request in microseconds (us) or milliseconds (ms) as appropriate (Latency)

The results displayed per iteration are sorted by IOPS. Each iteration starts with a row that displays the total IOPS used across all volumes. Other columns in this row are either totals or averages.

## Parameters

### **[-node {<nodename>|local}] - Node**

Selects the volumes that match this parameter value. If you do not specify this parameter, the command displays data for the entire cluster.

### **{ [-rows <integer>] - Number of Rows in the Output**

Specifies the number of busiest QoS policy groups to display. The default setting is 10. The allowed range of values is 1 to 20.

### **| -vserver <vserver name> - Vserver Name**

Specifies the Vserver to which the volume belongs.

### **-volume <volume name> - Volume Name }**

Selects the performance data that match this parameter value. Enter a complete volume name or press the <Tab> key to complete the name. Wildcard query characters are not supported.

### **[-iterations <integer>] - Number of Iterations**

Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

**[-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration**

Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

**[-show-flexgroup-as-constituents {true|false}] - Display Flexgroups as Constituents**

If the parameter is specified and if the value is true, it will display data for FlexVols and Flexgroup Constituents. Otherwise it will display data for FlexVols and Flexgroups.

## Examples

```
cluster1::> qos statistics volume performance show -iterations 100 -rows 3
Workload          ID      IOPS      Throughput      Latency
-----
-total-          -        97        1.90MB/s       216.87ms

vs1vol0-wid102  102      13        52.00KB/s     403.78ms
-total-          -        98       1276.00KB/s     89.98ms
vs1vol0-wid102  102      28       112.00KB/s     80.70ms
vol_1-wid103     103      19        76.00KB/s     114.72ms
vol_2-wid104     104      17       1088.00KB/s    257.60ms
-total-          -        78       1152.00KB/s    225.22ms
vol_1-wid103     103      17        68.00KB/s     452.27ms
vol_2-wid104     104      16       1024.00KB/s    419.93ms
vs1vol0-wid102  102      15        60.00KB/s     210.63ms
```

The example above displays the system performance for the **3** volumes with the highest IOPS and it refreshes the display **100** times before terminating.

```
cluster1::> qos statistics volume performance show -server vs0 -volume vs0_vol0
-iterations 100
Workload          ID      IOPS      Throughput      Latency
-----
-total-          -     1278     639.17KB/s     404.00us
vs0_vol0-wid1..  15658    526     263.17KB/s     436.00us
-total-          -     1315     657.33KB/s     86.00us
vs0_vol0-wid1..  15658    528     264.17KB/s     88.00us
-total-          -     1220     609.83KB/s    418.00us
vs0_vol0-wid1..  15658    515     257.33KB/s    531.00us
-total-          -     1202     600.83KB/s    815.00us
vs0_vol0-wid1..  15658    519     259.67KB/s    924.00us
-total-          -     1240     620.17KB/s    311.00us
vs0_vol0-wid1..  15658    525     262.50KB/s    297.00us
```

The example above displays the system performance for volume **vs0\_vol0** in Vserver **vs0** and it refreshes the display **100** times before terminating.

# qos statistics volume resource cpu show

Display CPU resource utilization data per volume

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `qos statistics volume resource cpu show` command displays the CPU utilization for volumes per node.

The command displays the following data:

- The QoS volume name (Workload)
- The QoS workload ID (ID)
- CPU utilization observed in percentage (CPU)

The results displayed per iteration are sorted by total CPU utilization. Each iteration starts with a row that displays the total CPU utilization across all volumes.

## Parameters

**-node {<nodename>|local} - Node**

Selects the volumes that match this parameter value.

**{ [-rows <integer>] - Number of Rows in the Output**

Specifies the number of busiest QoS policy groups to display. The default setting is 10. The allowed range of values is 1 to 20.

**| -vserver <vserver name> - Vserver Name**

Specifies the Vserver to which the volume belongs.

**-volume <volume name> - Volume Name }**

Selects the CPU utilization data that match this parameter value. Enter a complete volume name or press the <Tab> key to complete the name. Wildcard query characters are not supported.

**[-iterations <integer>] - Number of Iterations**

Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

**[-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration**

Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

**[-show-flexgroup-as-constituents {true|false}] - Display Flexgroups as Constituents**

If the parameter is specified and if the value is true, it will display data for FlexVols and Flexgroup

Constituents. Otherwise it will display data for FlexVols and Flexgroups.

## Examples

```
cluster1::> qos statistics volume resource cpu show -node nodeA -iterations 100 -rows
3
```

Workload	ID	CPU
-----	-----	-----
--total- (100%)	-	9%
vs0vol1-wid-102	102	5%
vs0vol2-wid-121	121	2%
vs2_vol0-wid-..	212	2%
-total- (100%)	-	8%
vs0vol1-wid-102	102	5%
vs0vol2-wid-121	121	2%
vs2_vol0-wid-..	212	1%

The example above displays total CPU utilization for the **3** volumes with the highest CPU utilization and it refreshes the display **100** times before terminating.

```
cluster1::> qos statistics volume resource cpu show -node local -vserver vs0 -volume
vs0_vol1 -iterations 100
```

Workload	ID	CPU
-----	-----	-----
-total- (100%)	-	2%
vs0_vol1-wid7..	7916	2%
-total- (100%)	-	2%
vs0_vol1-wid7..	7916	2%
-total- (100%)	-	1%
vs0_vol1-wid7..	7916	1%
-total- (100%)	-	2%
vs0_vol1-wid7..	7916	1%
-total- (100%)	-	2%
vs0_vol1-wid7..	7916	2%

The example above displays total CPU utilization for volume **vs0\_vol1** in Vserver **vs0** and it refreshes the display **100** times before terminating.

## qos statistics volume resource disk show

Display disk resource utilization data per volume

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `qos statistics volume resource disk show` command displays the disk utilization for volumes per node. The disk utilization shows the percentage of time spent on the disk during read and write operations. The command only supports hard disks.

The command displays the following data:

- The QoS volume name (Workload)
- The QoS workload ID (ID)
- Disk utilization (Disk)
- The number of HDD data disks utilized (Number of HDD Disks)

The results displayed are sorted by total disk utilization. Each iteration starts with a row that displays the total disk utilization across all volumes.

## Parameters

### `-node {<nodename>|local}` - Node

Selects the volumes that match this parameter value.

### `{ [-rows <integer>] - Number of Rows in the Output`

Specifies the number of busiest QoS policy groups to display. The default setting is 10. The allowed range of values is 1 to 20.

### `[-vserver <vserver name> - Vserver Name`

Specifies the Vserver to which the volume belongs.

### `-volume <volume name> - Volume Name }`

Selects the disk utilization data that match this parameter value. Enter a complete volume name or press the <Tab> key to complete the name. Wildcard query characters are not supported.

### `[-iterations <integer>] - Number of Iterations`

Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

### `[-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration`

Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

### `[-show-flexgroup-as-constituents {true|false}] - Display Flexgroups as Constituents`

If the parameter is specified and if the value is true, it will display data for FlexVols and Flexgroup Constituents. Otherwise it will display data for FlexVols and Flexgroups.

## Examples

```
cluster1::> qos statistics volume resource disk show -node nodeB -iterations 100 -rows 3
```

Workload	ID	Disk	Number of HDD	Disks
-total- (100%)	-	30%		4
vs0vol1-wid101	101	12%		2
vs0vol2-wid121	121	10%		1
vol0-wid1002	1002	8%		1
-total- (100%)	-	30%		4
vs0vol1-wid101	101	12%		2
vs0vol2-wid121	121	10%		1
vol0-wid1002	1002	8%		1

The example above displays total disk utilization for the **3** volumes with the highest disk utilization and it refreshes the display **100** times before terminating.

```
cluster1::> qos statistics volume resource disk show -node local -vserver vs0 -volume vs0_vol0 -iterations 100
```

Workload	ID	Disk	Number of HDD	Disks
-total-	-	5%		10
vs0_vol0-wid1..	15658	1%		6
-total-	-	5%		10
vs0_vol0-wid1..	15658	1%		6
-total-	-	6%		10
vs0_vol0-wid1..	15658	2%		6
-total-	-	6%		10
vs0_vol0-wid1..	15658	2%		6
-total-	-	6%		10
vs0_vol0-wid1..	15658	2%		6

The example above displays total disk utilization for volume **vs0\_vol0** in Vserver **vs0** and it refreshes the display **100** times before terminating.

## qos statistics workload characteristics show

Display QoS workload characterization

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **qos statistics workload characteristics show** command displays data that characterizes the behavior of QoS workloads.

The command displays the following data:

- The QoS workload name (Workload)
- The QoS workload ID (ID)
- Input/output operations performed per second (IOPS)
- Throughput achieved in kilobytes per second (KB/s) or megabytes per second (MB/s) as appropriate (Throughput)
- Request size in bytes (B) (Request size)
- Read percentage from total IOPS (Read)
- Concurrency, which indicates the number of concurrent users generating the I/O traffic (Concurrency)

The results displayed per iteration are sorted by IOPS. Each iteration starts with a row that displays the total IOPS used across all QoS workloads. Other columns in this row are either totals or averages.

## Parameters

### **[-node {<nodename>|local}] - Node**

Selects the QOS workloads that match this parameter value. If you do not specify this parameter, the command displays data for the entire cluster.

### **[-iterations <integer>] - Number of Iterations**

Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

### **[-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration**

Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

### **{ [-rows <integer>] - Number of Rows in the Output**

Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.

### **[-policy-group <text>] - QoS Policy Group Name**

Selects the QoS workloads that belong to the QoS policy group specified by this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

### **| [-adaptive-policy-group <text>] - Adaptive QoS Policy Group Name**

Selects the QoS workloads that belong to the QoS adaptive policy group specified by this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

### **| [-workload <text>] - QoS Workload Name**

Selects the QoS workload that match this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

**[ -workload-id <integer> ] - QoS Workload ID }**

Selects the QoS workload that match the QoS workload ID specified by this parameter value.

**[ -show-flexgroup-as-constituents {true|false} ] - Display Flexgroups as Constituents**

If the parameter is specified and if the value is true, it will display data for FlexVols and Flexgroup Constituents. Otherwise it will display data for FlexVols and Flexgroups.

## Examples

```

file-test1_b-..	9492	266	1064.00KB/s	4096B	100%	0

The example above displays the characteristics for the QoS workload with QoS workload ID **9492** and it refreshes the display **100** times before terminating.

## qos statistics workload latency show

Display latency breakdown data per QoS workload

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **qos statistics workload latency show** command displays the average latencies for QoS workloads on Data ONTAP subsystems.

The command displays the following data:

- The QoS workload name (Workload)
- The QoS workload ID (ID)
- Total latency observed per I/O operation (Latency)
- Latency observed per I/O operation in the Network subsystem (Network)
- Latency observed per I/O operation across the internally connected nodes in a Cluster (Cluster)
- Latency observed per I/O operation in the Data management subsystem (Data)
- Latency observed per I/O operation in the Storage subsystem (Disk)
- Latency observed per I/O operation for QoS Policy Group Ceiling (QoS Max)
- Latency observed per I/O operation for QoS Policy Group Floor (QoS Min)
- Latency observed per I/O operation for NVRAM transfer (NVRAM)
- Latency observed per I/O operation for Object Store(Cloud) operations
- Latency observed per I/O operation for FlexCache (FlexCache) operations
- Latency observed per I/O operation for Synchronous Snapmirror (SM Sync) operations

- Latency observed per I/O operation for Volume Activation (VA) operations

The results displayed per iteration are sorted by the total latency field. Each iteration starts with a row that displays the average latency, in microseconds (us) or milliseconds (ms) observed across all QoS workloads.

## Parameters

### **[-node {<nodename>|local}] - Node**

Selects the QoS workloads that match this parameter value. If you do not specify this parameter, the command displays data for the entire cluster.

### **[-iterations <integer>] - Number of Iterations**

Specifies the number of times that the command refreshes the display with updated data before terminating. If you do not specify this parameter, the command continues to run until you interrupt it by pressing Ctrl-C.

### **[-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration**

Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

### **{ [-rows <integer>] - Number of Rows in the Output**

Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.

### **[-policy-group <text>] - QoS Policy Group Name**

Selects the QoS workloads that belong to the QoS policy group specified by this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

### **| [-adaptive-policy-group <text>] - Adaptive QoS Policy Group Name**

Selects the QoS workloads that belong to the QoS adaptive policy group specified by this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

### **| [-workload <text>] - QoS Workload Name**

Selects the QoS workload that match this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

### **| [-workload-id <integer>] - QoS Workload ID }**

Selects the QoS workload that match the QoS workload ID specified by this parameter value.

### **[-show-flexgroup-as-constituents {true|false}] - Display Flexgroups as Constituents**

If the parameter is specified and if the value is true, it will display data for FlexVols and Flexgroup Constituents. Otherwise it will display data for FlexVols and Flexgroups.

# Examples

```

## qos statistics workload performance show

Display system performance data per QoS workload

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `qos statistics workload performance show` command shows the current system performance that each QoS workload is achieving.

The command displays the following data:

- The QoS workload name (Workload)
- The QoS workload ID (ID)
- Input/output operations performed per second (IOPS)
- Throughput in kilobytes per second (KB/s) or megabytes per second (MB/s) as appropriate (Throughput)
- Latency observed per request in microseconds (us) or milliseconds (ms) as appropriate (Latency)

The results displayed per iteration are sorted by IOPS. Each iteration starts with a row that displays the total IOPS used across all QoS workloads. Other columns in this row are either totals or averages.

## Parameters

### **`[-node {<nodename>|local}]` - Node**

Selects the QOS workloads that match this parameter value. If you do not specify this parameter, the command displays data for the entire cluster.

### **`[-iterations <integer>]` - Number of Iterations**

Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

### **`[-refresh-display {true|false}]` - Toggle Screen Refresh Between Each Iteration**

Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

### **`{ [-rows <integer>]}` - Number of Rows in the Output**

Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.

### **`[-policy-group <text>]` - QoS Policy Group Name**

Selects the QoS workloads that belong to the QoS policy group specified by this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

### **`[-adaptive-policy-group <text>]` - Adaptive QoS Policy Group Name**

Selects the QoS workloads that belong to the QoS adaptive policy group specified by this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

### **`[-workload <text>]` - QoS Workload Name**

Selects the QoS workload that match this parameter value. If you do not specify this parameter,

the command displays data for all QoS workloads.

### [**-workload-id <integer>**] - QoS Workload ID }

Selects the QoS workload that match the QoS workload ID specified by this parameter value.

### [**-show-flexgroup-as-constituents {true|false}**] - Display Flexgroups as Constituents

If the parameter is specified and if the value is true, it will display data for FlexVols and Flexgroup Constituents. Otherwise it will display data for FlexVols and Flexgroups.

## Examples

-total-	-	2810	10.58MB/s	832.00us
file-testfile..	11201	685	2.68MB/s	909.00us
-total-	-	2593	9.86MB/s	1092.00us
file-testfile..	11201	632	2.47MB/s	964.00us

The example above displays the system performance for the QoS workload with QoS workload ID **11201** and it refreshes the display **100** times before terminating.

## qos statistics workload resource cpu show

Display CPU resource utilization data per QoS workload

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The `qos statistics workload resource cpu show` command displays the CPU utilization for QoS workloads per node.

The command displays the following data:

- The QoS workload name (Workload)
- The QoS workload ID (ID)
- CPU utilization observed in percentage (CPU)

The results displayed per iteration are sorted by total CPU utilization. Each iteration starts with a row that displays the total CPU utilization across all QoS workloads.

### Parameters

**-node {<nodename>|local} - Node**

Selects the QOS workloads that match this parameter value.

**[-iterations <integer>] - Number of Iterations**

Specifies the number of times the display is refreshed before terminating. If you do not specify

this parameter, the command iterates until interrupted by Ctrl-C.

### **[-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration**

Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

### **{ [-rows <integer>] - Number of Rows in the Output**

Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.

### **[-policy-group <text>] - QoS Policy Group Name**

Selects the QoS workloads that belong to the QoS policy group specified by this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

### **| [-adaptive-policy-group <text>] - Adaptive QoS Policy Group Name**

Selects the QoS workloads that belong to the QoS adaptive policy group specified by this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

### **| [-workload <text>] - QoS Workload Name**

Selects the QoS workload that match this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

### **| [-workload-id <integer>] - QoS Workload ID }**

Selects the QoS workload that match the QoS workload ID specified by this parameter value.

### **[-show-flexgroup-as-constituents {true|false}] - Display Flexgroups as Constituents**

If the parameter is specified and if the value is true, it will display data for FlexVols and Flexgroup Constituents. Otherwise it will display data for FlexVols and Flexgroups.

## Examples

```
cluster1::> qos statistics workload resource cpu show -node nodeA -iterations 100
-rows 3
  Workload          ID  CPU
  -----
--total- (100%)    -   9%
vs0-wid-102        102  5%
file-bigvmdk-..   121  2%
vs2_vol0-wid-..   212  2%
-total- (100%)    -   8%
vs0-wid-101        102  5%
file-bigvmdk-..   121  2%
vs2_vol0-wid-..   212  1%
```

The example above displays total CPU utilization for the **3** QoS workloads with the highest CPU utilization and it refreshes the display **100** times before terminating.

```
cluster1::> qos statistics workload resource cpu show -node local -iterations 100
-rows 2 -policy-group pg1
  Workload          ID    CPU
  -----
-total- (100%)      -    41%
file-test1_b-..    9492  16%
file-test1_c-..    5078  16%
-total- (100%)      -    43%
file-test1_c-..    5078  17%
file-test1_b-..    9492  16%
-total- (100%)      -    40%
file-test1_c-..    5078  16%
file-test1_b-..    9492  15%
```

The example above displays total CPU utilization for the **2** QoS workloads belonging to QoS policy group **pg1** with the highest IOPS and it refreshes the display **100** times before terminating.

```
cluster1::> qos statistics workload resource cpu show -node local -iterations 100
-workload-id 9492
  Workload          ID    CPU
  -----
-total- (100%)      -    15%
file-test1_b-..    9492   3%
-total- (100%)      -    14%
file-test1_b-..    9492   3%
-total- (100%)      -    14%
file-test1_b-..    9492   2%
-total- (100%)      -    13%
file-test1_b-..    9492   3%
```

The example above displays total CPU utilization for the QoS workload with QoS workload ID **9492** and it refreshes the display **100** times before terminating.

## qos statistics workload resource disk show

Display disk resource utilization data per QoS workload

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The `qos statistics workload resource disk show` command displays the disk utilization for QoS workloads per node. The disk utilization shows the percentage of time spent on the disk during read and write operations. The command displays disk utilization for system-defined workloads; however, their disk utilization is not included in the total utilization. The command only supports hard disks.

The command displays the following data:

- The QoS workload name (Workload)
- The QoS workload ID (ID)
- Disk utilization (Disk)
- The number of HDD data disks utilized (Number of HDD Disks)

The results displayed are sorted by total disk utilization. Each iteration starts with a row that displays the total disk utilization across all QoS workloads.

## Parameters

### **-node {<nodename>|local} - Node**

Selects the QOS workloads that match this parameter value.

### **[-iterations <integer>] - Number of Iterations**

Specifies the number of times the display is refreshed before terminating. If you do not specify this parameter, the command iterates until interrupted by Ctrl-C.

### **[-refresh-display {true|false}] - Toggle Screen Refresh Between Each Iteration**

Specifies the display style. If true, the command clears the display after each data iteration. If false, the command displays each data iteration below the previous one. The default is false.

### **{ [-rows <integer>] - Number of Rows in the Output**

Specifies the number of busiest QoS policy groups to display. Valid values are from 1 to 20. The default value is 10.

### **[-policy-group <text>] - QoS Policy Group Name**

Selects the QoS workloads that belong to the QoS policy group specified by this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

### **| [-adaptive-policy-group <text>] - Adaptive QoS Policy Group Name**

Selects the QoS workloads that belong to the QoS adaptive policy group specified by this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

### **| [-workload <text>] - QoS Workload Name**

Selects the QoS workload that match this parameter value. If you do not specify this parameter, the command displays data for all QoS workloads.

### **| [-workload-id <integer>] - QoS Workload ID }**

Selects the QoS workload that match the QoS workload ID specified by this parameter value.

### **[-show-flexgroup-as-constituents {true|false}] - Display Flexgroups as Constituents**

If the parameter is specified and if the value is true, it will display data for FlexVols and Flexgroup Constituents. Otherwise it will display data for FlexVols and Flexgroups.

## Examples

```
cluster1::> qos statistics workload resource disk show -node nodeB -iterations 100
-rows 3
```

Workload	ID	Disk	Number of HDD	Disks
-total- (100%)	-	30%		4
_RAID	-	20%		4
vs0-wid101	101	12%		2
file-1-wid121	121	10%		1
vol0-wid1002	1002	8%		1
_WAFL	-	7%		3
-total- (100%)	-	30%		4
vs0-wid101	101	12%		2
file-1-wid121	121	10%		1
_RAID	-	10%		4
vol0-wid1002	1002	8%		1
_WAFL	-	7%		3

The example above displays total disk utilization for the **3** QoS workloads with the highest disk utilization and it refreshes the display **100** times before terminating.

```
cluster1::> qos statistics workload resource disk show -node local -iterations 100
-rows 2 -policy-group pg1
```

Workload	ID	Disk	Number of HDD	Disks
-total-	-	3%		10
file-test1_a-..	6437	6%		6
file-test1-wi..	7872	6%		6
-total-	-	3%		10
file-test1_a-..	6437	5%		6
file-test1-wi..	7872	5%		6
-total-	-	3%		10
file-test1_a-..	6437	6%		6
file-test1-wi..	7872	6%		6

The example above displays total disk utilization for the **2** QoS workloads belonging to QoS policy group **pg1** with the highest IOPS and it refreshes the display **100** times before terminating.

```
cluster1::> qos statistics workload resource disk show -node local -iterations 100
-workload-id 6437
```

Workload	ID	Disk	Number of HDD	Disks
-total-	-	3%		10
file-test1_a-..	6437	6%		6
-total-	-	3%		10
file-test1_a-..	6437	5%		6

-total-	-	3%	10
file-test1_a-..	6437	6%	6

The example above displays total disk utilization for the QoS workload with QoS workload ID **6437** and it refreshes the display **100** times before terminating.

## qos workload delete

Delete workload

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

Deletes a workload from a cluster. When you delete a workload, the associated data object is no longer controlled by its policy group.

You can only delete user-defined workloads. You cannot delete system-defined or preset workloads.

### Parameters

**-workload <text> - Workload Name**

Specifies the name of the workload that you want to delete.

### Examples

```
cluster1::> qos workload delete workload1
```

Deletes the "workload1" user-defined workload from the "cluster1" cluster.

## qos workload show

Display a list of workloads

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

Shows the current status of workloads on a cluster. Use this command to determine the types of workloads that are currently on a cluster. The types of workloads include: system-defined, preset, and user-defined. The system generates system-defined and preset workloads. You cannot create, modify, or delete these workloads. Also, you can only modify or delete a user-defined workload, but cannot create one

## Parameters

### { [-fields <fieldname>, ... ] }

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

### [ [-instance ] ] }

If you specify the **-instance** parameter, the command displays detailed information about all fields.

### [ -workload <text> ] - Workload Name

If you use this parameter, the command displays the workloads that contain the specified workload name.

### [ -uuid <UUID> ] - Workload UUID

If you use this parameter, the command displays the workloads that contain the specified UUID.

### [ -class <QoS Configuration Class> ] - Workload Class

If you use this parameter, the command displays the workloads that contain the specified class. The Class options include system-defined, preset, and user-defined.

### [ -wid <integer> ] - Workload ID

If you use this parameter, the command displays the workloads that contain the specified internal workload ID.

### [ -category <text> ] - Workload Category

If you use this parameter, the command displays the workloads that contain the specified category. The category options include Scanner and Efficiency.

### [ -policy-group <text> ] - Policy Group Name

If you use this parameter, the command displays the workloads that match the specified policy group name.

### [ -read-ahead <text> ] - Read-ahead Tunables

If you use this parameter, the command displays the workloads that contain the specified read-ahead cache tunable.

### [ -vserver <vserver name> ] - Vserver

If you use this parameter, the command displays the workloads that match the specified Vserver.

### [ -volume <volume name> ] - Volume

If you use this parameter, the command displays the workloads that match the specified volume.

### [ -qtree <qtree name> ] - Qtree Name

If you use this parameter, the command displays the workloads that match the specified Qtree name.

**[-lun <text>] - LUN Name**

If you use this parameter, the command displays the workloads that match the specified LUN name.

**[-file <text>] - File Path**

If you use this parameter, the command displays the workloads that match the specified file path.

**[-max-throughput <qos\_tput>] - Maximum Throughput**

Selects the workloads that match this parameter value

A maximum throughput limit specifies the throughput in IOPS that the workload must not exceed.

**[-min-throughput <qos\_tput>] - Minimum Throughput**

Selects the workloads that match this parameter value

A minimum throughput specifies the desired performance level for a workload in IOPS.

**[-is-adaptive {true|false}] - Adaptive**

If you use this parameter, the command displays only adaptive workloads.

**[-is-constituent {true|false}] - Is Constituent Volume**

If this parameter is specified, the command displays information only about storage objects that either are or are not constituents of a FlexGroup, depending on the value provided.

## Examples

```
cluster1::> qos workload show -class user-defined
Workload      Wid  Policy Group Vserver  Volume  LUN  Qtree  File Path
-----
vs2-wid100    100  pg1          vs2      -       -     -       -
```

Shows all user-defined workloads and the corresponding storage objects on the "cluster1" cluster.

## san config enable-san-optimized

Enable the All SAN Array personality for the cluster

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **san config enable-san-optimized** command converts the cluster to an All SAN Array. Conversion is a one-way, irreversible process. All SAN Array does not support NAS protocols. Prior to conversion, remove all NAS services and LIFs.

## Parameters

## Examples

The following example converts the cluster to an All SAN Array.

```
cluster1::*> san config enable-san-optimized
```

## san config show

Show SAN configuration options for the cluster

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The command displays cluster SAN configuration options.

## Examples

The following example displays the cluster SAN configuration.

```
cluster1:::> san config show
  All SAN Array: true
```

## security snmpusers

Show SNMP users

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **security snmpusers** displays the following information about SNMP users:

- User name
- Authentication method
- Hexadecimal engine ID
- Authentication protocol
- Privacy protocol

- Security group

## Parameters

### { [-fields <fieldname>, ... ] }

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

### [ [-instance ] ] }

If you specify the **-instance** parameter, the command displays detailed information about all fields.

### [-vserver <Vserver Name>] - Vserver

If this parameter is specified, the command displays information only about the SNMP user or users that belong to the specified Vserver.

### [-username <text>] - User Name

If this parameter is specified, the command displays information only about the SNMP user with the specified user name.

### [-authmethod <text>] - Authentication Method

If this parameter is specified, the command displays information only about the SNMP user or users that use the specified authentication method. Possible values include the following:

- community-SNMP community strings
- usm-SNMP user security model

### [-remote-switch-ipaddress <IP Address>] - Remote Switch IP Address

If this parameter is specified, the command displays information only about the remote SNMP user or users that belong to the specified remote switch.

### [-engineid <Hex String>] - Engine Id

If this parameter is specified, the command displays information only about the SNMP user or users that use the specified engine ID, specified in hexadecimal format.

### [-authprotocol <text>] - Authentication Protocol

If this parameter is specified, the command displays information only about the SNMP user or users that use the specified authentication protocol.

### [-privprotocol <text>] - Privacy Protocol

If this parameter is specified, the command displays information only about the SNMP user or users that use the specified privacy protocol.

### [-securitygroup <text>] - Security Group

If this parameter is specified, the command displays information only about the SNMP user or users that belong to the specified security group.

## Examples

The following example displays information about all SNMP users:

```
cluster1::> security snmpusers
```

Vserver	UserName	AuthMethod	EngineId	Protocols			Security Group	Remote Switch IP
				Auth	Priv	Group		
cluster1	comm1	community	8000031504312d38302d313233343536	-	-	readwrite	-	
cluster1	private	community	8000031504312d38302d313233343536	-	-	readwrite	-	
cluster1	snmpuser1	usm	80000634b21000000533296869	-	-	readwrite	172.2.20.91	
vs1	snmpuser2	community	8000031504312d38302d31323334353632	-	-	readwrite	-	
vs1	snmpuser3	usm	8000031504312d38302d31323334353632	-	-	readwrite	-	

## security anti-ransomware volume disable

Disable anti-ransomware on a volume

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

### Description

The **security anti-ransomware volume disable** command disables anti-ransomware monitoring on a volume.

### Parameters

**-vserver <vserver name> - Vserver Name**

Anti-ransomware monitoring is disabled on volumes that match the values for the Vserver and volume parameters. If only one data Vserver exists, you do not need to specify this parameter.

**-volume <volume name> - Volume Name**

Anti-ransomware monitoring is disabled on volumes matching the parameter value.

### Examples

# security anti-ransomware volume dry-run

Dry-run anti-ransomware on a volume

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **security anti-ransomware volume dry-run** command starts anti-ransomware monitoring in the evaluation mode on a volume.

## Parameters

**-vserver <vserver name> - Vserver Name**

Anti-ransomware monitoring is enabled in the evaluation mode on volumes that match the values for the Vserver and volume parameters. If only one data Vserver exists, you do not need to specify this parameter.

**-volume <volume name> - Volume Name**

Anti-ransomware monitoring is enabled in the evaluation mode on volumes matching the parameter value.

## Examples

# security anti-ransomware volume enable

Enable anti-ransomware on a volume

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **security anti-ransomware volume enable** command enables anti-ransomware monitoring on a volume.

## Parameters

**-vserver <vserver name> - Vserver Name**

Anti-ransomware monitoring is enabled on volumes that match the values for the Vserver and volume parameters. If only one data Vserver exists, you do not need to specify this parameter.

**-volume <volume name> - Volume Name**

Anti-ransomware monitoring is enabled on volumes matching the parameter value.

## Examples

# security anti-ransomware volume pause

Pause anti-ransomware on a volume

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **security anti-ransomware volume pause** command pauses Anti-ransomware monitoring on a volume.

## Parameters

**-vserver <vserver name> - Vserver Name**

Anti-ransomware monitoring is paused in the evaluation mode on volumes that match the values for the Vserver and volume parameters. If only one data Vserver exists, you do not need to specify this parameter.

**-volume <volume name> - Volume Name**

Anti-ransomware monitoring is paused on volumes matching the parameter value.

## Examples

# security anti-ransomware volume resume

Resume anti-ransomware on a volume

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **security anti-ransomware volume resume** command resumes Anti-ransomware monitoring on a volume.

## Parameters

### **-vserver <vserver name> - Vserver Name**

Anti-ransomware monitoring is resumed on volumes that match the values for the Vserver and volume parameters. If only one data Vserver exists, you do not need to specify this parameter.

### **-volume <volume name> - Volume Name**

Anti-ransomware monitoring is resumed on volumes matching the parameter value.

## Examples

# security anti-ransomware volume show

Show anti-ransomware related information of volumes

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `security anti-ransomware volume show` command displays information related to Anti-ransomware on the volumes in the cluster. The following information is displayed:

- Vserver Name: The Vserver on which the volume is located.
- Volume Name: The volume name
- State: The Anti-ransomware state of the volume. The possible values are **disabled**, **enabled**, **dry-run**, **dry-run-paused**, **enable-paused** and **disable-in-progress**.

## Parameters

**{ [-fields <fieldname>, ... ]**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ [-attack ]**

If this parameter is specified, ransomware attack details are displayed.

**[ [-instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-vserver <vserver name>] - Vserver Name**

If this parameter and the **-volume** parameter are specified, the command displays detailed information related to Anti-ransomware about the specified volume. If this parameter is specified

by itself, the command displays information related to the Anti-ransomware about all volumes on the specified Vserver.

#### **[-volume <volume name>] - Volume Name**

If this parameter and the **-vserver** parameter are specified, the command displays detailed information related to Anti-ransomware about the specified volume. If this parameter is specified by itself, the command displays information related to the Anti-ransomware about all volumes matching the specified name.

#### **[-state {disabled|enabled|dry-run|paused|dry-run-paused|enable-paused|disable-in-progress}] - State**

If this parameter is specified, the command displays information only about the volume or volumes that have the specified Anti-ransomware state. The possible values are **disabled**, **enabled**, **dry-run**, **dry-run-paused**, **enable-paused** and **disable-in-progress**. The possible states are:

- disabled - Anti-ransomware is disabled on the volume.
- enabled - Anti-ransomware is enabled on the volume.
- dry-run - Anti-ransomware is enabled in the dry-run or evaluation mode on the volume.
- dry-run-paused - Anti-ransomware is paused from dry-run or evaluation mode on the volume.
- enable-paused - Anti-ransomware is paused on the volume.
- disable-in-progress - Anti-ransomware disable work is in progress on the volume.

#### **[-dry-run-start-time <MM/DD/YYYY HH:MM:SS>] - Dry Run Start Time**

If this parameter is specified, the command displays the dry run start time of the volumes that have the state dry-run or dry-run-paused.

#### **[-attack-probability {none|low|moderate|high}] - Attack Probability**

If this parameter is specified, the command displays information only about the volumes that have the specified probability. The possible values are **none**, **low**, **moderate**, and **high**.

- none - No data is suspected for ransomware activity.
- low - Small amount data is suspected for ransomware activity.
- moderate - Moderate amount of data is suspected for ransomware activity.
- high - Large amount data is suspected for ransomware activity.

#### **[-attack-timeline <MM/DD/YYYY HH:MM:SS>, ...] - Attack Timeline**

If this parameter is specified, the command displays information only about the volumes that have the specified attack-timeline.

#### **[-no-of-attacks <integer>] - Number of Attacks**

This provides the number of ransomware attacks observed.

## Examples

The following example shows a sample output for this command:

```
cluster1::> security anti-ransomware volume show
```

Vserver	Volume	State
vs1	vol1	enabled

# security anti-ransomware volume attack clear-suspect

Clear suspect record

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **anti-ransomware volume attack clear-suspect** command removes the specified files from suspect files report. When no optional parameters are provided, the suspect report file is cleared.

## Parameters

**-vserver <vserver name> - Vserver Name**

This parameter specifies the Vserver on which the volume is located.

**-volume <volume name> - Volume Name**

This parameter specifies the name of the volume on which anti-ransomware feature is enabled.

**{ [-sequence-number <integer>] - Sequence Number**

This optionally specifies the sequence number of the suspect file obtained from generated report.

**{ [-extensions <text>, ...] - File Extensions**

This optionally specifies the extensions of ransomware attacked files that needs to be cleared from attack report.

**[ [-start-time <MM/DD/YYYY HH:MM:SS>] - Start Time**

This optionally specifies the lower bound of the time to clear a suspect record. Any suspect record with time greater than or equal to start-time is cleared.

**[-end-time <MM/DD/YYYY HH:MM:SS>] - End Time }**

This optionally specifies upper bound of the time to clear a suspect record. Any suspect record with time less than or equal to end-time is cleared.

**-false-positive {true|false} - False Positive?**

This indicates whether the suspect record of specific extensions, time range, and so on, are to be

considered a false positive.

## Examples

The following example shows a sample output for clearing all the suspects observed with timestamp in the start-time and end-time range, and with given extension.

```
clus1::> security anti-ransomware volume attack clear-suspect -volume testvol -start
-time "4/14/2021 04:16:48" -end-time "4/14/2021 06:16:50"
5 suspect records cleared.
```

The following examples shows output when given sequence-number is not present.

```
clus1:*> security anti-ransomware volume attack clear-suspect -volume testvol
-sequence-number 1000
```

```
Error: command failed: No suspect records found.
```

# security anti-ransomware volume attack generate-report

Generates Report File of the Suspected Attack on the Volume

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **anti-ransomware volume attack generate-report** command copies the report file to the given path.

## Parameters

**-vserver <vserver name> - Vserver Name**

This parameter specifies the Vserver on which the volume is located.

**-volume <volume name> - Volume Name**

This parameter specifies the name of the volume on which anti-ransomware feature is enabled.

**-dest-path <[vserver:]volume/path/to/filename> - Destination path under the volume to copy the file**

This parameter specifies the path where requested file is to be copied.

## Examples

The following example displays command output:

```
node::*> security anti-ransomware volume attack generate-report -volume vol1 -dest
-path vs1:vol1/
Report "report_file_vs1vol1_30-03-2021_16-11-38" available at path "vs1:vol1/".
```

# security anti-ransomware volume attack-detection-parameters modify

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **security anti-ransomware volume attack-detection-parameters modify** command can be used to modify the attack detection parameters of an anti-ransomware enabled volume.

## Parameters

### **-vserver <Vserver Name> - Vserver Name**

This parameter specifies the Vserver of the anti-ransomware enabled volume.

### **-volume <volume name> - Volume Name**

This parameter specifies the anti-ransomware enabled volume for which the attack detection parameters need to be modified.

### **[-based-on-high-entropy-data-rate {true|false}] - High Entropy Data Rate at Volume Level**

This parameter indicates whether ransomware detection is based on a high entropy data rate at the volume level. Ransomware detection is also done based on high entropy data rate at the file level and this method of detection is always enabled and has no dependency on this parameter.

### **[-based-on-never-seen-before-file-extension {true|false}] - Never Seen before File Extension**

This parameter indicates whether ransomware detection is based on new file types not seen before at the volume level. This detection method is based only on the file extension not on the file entropy. Some variants of ransomware modify the data such that the file entropy remains unchanged. This method helps in detecting those ransomwares but there is a possibility of false positives. Note that ransomware detection is also done based on combined file extension and file entropy and this method of detection is always enabled and has no dependency on this parameter.

**[-based-on-file-create-rate {true|false}] - Is Based on File Create Operation Rate**

This parameter indicates whether ransomware detection is based on the file create rate at the volume level. If this is true and the number of files created per timeslot surges by **-file-create-rate-surge-notify-percentage** percentage compared to the historically observed value, then it is considered an attack.

**[-based-on-file-rename-rate {true|false}] - Is Based on File Rename Operation Rate**

This parameter indicates whether ransomware detection is based on the file rename rate at the volume level. If this is true and the number of files renamed per timeslot surges by **-file-rename-rate-surge-notify-percentage** percentage compared to the historically observed value, then it is considered an attack.

**[-based-on-file-delete-rate {true|false}] - Is Based on File Delete Operation Rate**

This parameter indicates whether ransomware detection is based on the file delete rate at the volume level. If this is true and the number of files deleted per timeslot surges by **-file-delete-rate-surge-notify-percentage** percentage compared to the historically observed value, then it is considered an attack.

**[-relaxing-popular-file-extensions {true|false}] - Is Relaxing Popular File Extensions**

This parameter indicates whether ransomware detection is based on commonly used extensions. If true, then a predetermined commonly used extension, such as .mp3, is considered safe. If false, only those file extensions observed during the dry-run state are considered safe; any extension not observed during the dry-run state but observed later is a suspected ransomware attack, even if it is a commonly used extension.

**[-high-entropy-data-surge-notify-percentage <integer>] - High Entropy Data Surge Notify Percentage**

This parameter displays the surge value that is considered safe in the overall incoming data at the volume level.

**[-file-create-rate-surge-notify-percentage <integer>] - File Create Operation Rate Surge Notify Percentage**

This parameter displays the surge rate that is considered safe for file create operations at the volume level.

**[-file-delete-rate-surge-notify-percentage <integer>] - File Delete Operation Rate Surge Notify Percentage**

This parameter displays the surge rate that is considered safe for file delete operations at the volume level.

**[-file-rename-rate-surge-notify-percentage <integer>] - File Rename Operation Rate Surge Notify Percentage**

This parameter displays the surge rate that is considered safe for file rename operations at the volume level.

**[-never-seen-before-file-extn-count-notify-threshold <integer>] - Never Seen before File Extension Count Notify Threshold**

This parameter displays the threshold value of number of files observed with a new file extension not seen before for create/rename operations.

### **[-never-seen-before-file-extn-duration-in-hours <integer>] - Never Seen before File Extension Duration in Hours**

This parameter displays the duration for new file extensions not seen before, in hours. If a new file extension is observed and **-never-seen-before-file-extn-count-notify-threshold** number of files are created/renamed with this new file extension for this duration, then it is reported as an attack.

## Examples

The following example displays attack detection parameter information of a volume.

```
cluster1::> security anti-ransomware volume attack-detection-parameters show -vserver
vs1 -volume vol1
```

```

                                Vserver Name : vs1
                                Volume Name : vol1
    Is Detection Based on High Entropy Data Rate? : true
Is Detection Based on Never Seen before File Extension? : true
    Is Detection Based on File Create Rate? : true
    Is Detection Based on File Rename Rate? : true
    Is Detection Based on File Delete Rate? : true
    Is Detection Relaxing Popular File Extensions? : true
    High Entropy Data Surge Notify Percentage : 100
    File Create Rate Surge Notify Percentage : 100
    File Rename Rate Surge Notify Percentage : 100
    File Delete Rate Surge Notify Percentage : 100
Never Seen before File Extensions Count Notify Threshold : 20
    Never Seen before File Extensions Duration in Hour : 24
```

```
cluster1::> security anti-ransomware volume attack-detection-parameters modify
-vserver vs1 -volume vol1 -file-delete-rate-surge-notify-percentage 25
```

```
cluster1::> security anti-ransomware volume attack-detection-parameters show -vserver
vs1 -volume vol1
```

```

                                Vserver Name : vs1
                                Volume Name : vol1
    Is Detection Based on High Entropy Data Rate? : true
Is Detection Based on Never Seen before File Extension? : true
    Is Detection Based on File Create Rate? : true
    Is Detection Based on File Rename Rate? : true
    Is Detection Based on File Delete Rate? : true
    Is Detection Relaxing Popular File Extensions? : true
    High Entropy Data Surge Notify Percentage : 100
    File Create Rate Surge Notify Percentage : 100
    File Rename Rate Surge Notify Percentage : 100
    File Delete Rate Surge Notify Percentage : 25
Never Seen before File Extensions Count Notify Threshold : 20
```

Never Seen before File Extensions Duration in Hour : 24

# security anti-ransomware volume attack-detection-parameters show

Show anti-ransomware volume attack detection parameters

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `security anti-ransomware volume attack-detection-parameters show` command displays attack detection parameter details of an anti-ransomware enabled volume.

## Parameters

`{ [-fields <fieldname>, ... ] }`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

`[ -instance ] }`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`-vserver <Vserver Name> - Vserver Name`

This parameter specifies the Vserver of the anti-ransomware enabled volume.

`-volume <volume name> - Volume Name`

This parameter specifies the anti-ransomware enabled volume for which the attack detection parameters need to be displayed.

`[ -based-on-high-entropy-data-rate {true|false} ] - High Entropy Data Rate at Volume Level`

This parameter displays whether ransomware detection is based on a high entropy data rate at the volume level. Ransomware detection is also done based on high entropy data rate at the file level and this method of detection is always enabled and has no dependency on this parameter.

`[ -based-on-never-seen-before-file-extension {true|false} ] - Never Seen before File Extension`

This parameter indicates whether ransomware detection is based on new file types not seen before at the volume level. This detection method is based only on the file extension not on file entropy. Some variants of ransomware modify the data such that the file entropy remains unchanged. This method helps in detecting those ransoms but there is a possibility of false positives. Note that ransomware detection is also done based on combined file extension and file entropy and this method of detection is always enabled and has no dependency on this

parameter.

#### **[-based-on-file-create-rate {true|false}] - Is Based on File Create Operation Rate**

This parameter displays whether ransomware detection is based on the file create rate at the volume level. If this is true and the number of files created per timeslot surges by **-file-create-rate-surge-notify-percentage** percentage compared to the historically observed value, then it is considered an attack.

#### **[-based-on-file-rename-rate {true|false}] - Is Based on File Rename Operation Rate**

This parameter displays whether ransomware detection is based on the file rename rate at the volume level. If this is true and the number of files renamed per timeslot surges by **-file-rename-rate-surge-notify-percentage** percentage compared to the historically observed value, then it is considered an attack.

#### **[-based-on-file-delete-rate {true|false}] - Is Based on File Delete Operation Rate**

This parameter displays whether ransomware detection is based on the file delete rate at the volume level. If this is true and the number of files deleted per timeslot surges by **-file-delete-rate-surge-notify-percentage** percentage compared to the historically observed value, then it is considered an attack.

#### **[-relaxing-popular-file-extensions {true|false}] - Is Relaxing Popular File Extensions**

This parameter displays whether ransomware detection is based on commonly used extensions. If true, then a predetermined commonly used extension, such as .mp3, is considered safe. If false, only those file extensions observed during the dry run state are considered safe; any extension not observed during the dry-run state but observed later is suspected as a ransomware attack, even if it is a commonly used extension.

#### **[-high-entropy-data-surge-notify-percentage <integer>] - High Entropy Data Surge Notify Percentage**

This parameter displays the surge value that is considered safe in the overall incoming data at the volume level.

#### **[-file-create-rate-surge-notify-percentage <integer>] - File Create Operation Rate Surge Notify Percentage**

This parameter displays the surge rate that is considered safe for file create operations at the volume level.

#### **[-file-delete-rate-surge-notify-percentage <integer>] - File Delete Operation Rate Surge Notify Percentage**

This parameter displays the surge rate that is considered safe for file delete operations at the volume level.

#### **[-file-rename-rate-surge-notify-percentage <integer>] - File Rename Operation Rate Surge Notify Percentage**

This parameter displays the surge rate that is considered safe for file rename operations at the volume level.

### **[-never-seen-before-file-extn-count-notify-threshold <integer>] - Never Seen before File Extension Count Notify Threshold**

This parameter displays the threshold value of new file extensions not seen before for create/rename operations.

### **[-never-seen-before-file-extn-duration-in-hours <integer>] - Never Seen before File Extension Duration in Hours**

This parameter displays the duration for new file extensions not seen before, in hours. If a new file extension is observed and **-never-seen-before-file-extn-count-notify-threshold** number of files are created/renamed with this new file extension for this duration, then it is reported as an attack.

## Examples

The following example displays attack detection parameter information of a volume.

```
cluster1::> security anti-ransomware volume attack-detection-parameters show -vserver
vs1 -volume vol1
                Vserver Name : vs1
                Volume Name : vol1
    Is Detection Based on High Entropy Data Rate? : true
    Is Detection Based on Never Seen before File Extension? : true
        Is Detection Based on File Create Rate? : true
        Is Detection Based on File Rename Rate? : true
        Is Detection Based on File Delete Rate? : true
    Is Detection Relaxing Popular File Extensions? : true
    High Entropy Data Surge Notify Percentage : 100
    File Create Rate Surge Notify Percentage : 100
    File Rename Rate Surge Notify Percentage : 100
    File Delete Rate Surge Notify Percentage : 100
    Never Seen before File Extensions Count Notify Threshold : 20
    Never Seen before File Extensions Duration in Hour : 24
```

## security anti-ransomware volume space show

Display the details of anti-ransomware space usage

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This **security anti-ransomware volume space show** displays the space usage by Anti-ransomware feature.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ [-instance ] ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-vserver <vserver name>] - Vserver Name**

This parameter specifies the Vserver on which the volume is located.

**[-volume <volume name>] - Volume Name**

This parameter specifies the name of the volume whose space usage details are to be shown.

**[-space-used-by-snapshot {<integer>[KB|MB|GB|TB|PB]}] - Space Used by snapshots**

This parameter shows space usage by Anti-ransomware Snapshot copies.

**[-space-used-by-logs {<integer>[KB|MB|GB|TB|PB]}] - Space Used by logs**

This parameter shows the space used by the Anti-ransomware logs.

**[-total-space-used {<integer>[KB|MB|GB|TB|PB]}] - Total space used by anti-ransomware**

This parameter shows the total space used by the Anti-ransomware feature.

**[-no-of-snapshot <integer>] - Number of Anti-ransomware Snapshot Copies**

This parameter shows the total count of the Anti-ransomware Snapshot copies.

## Examples

The following example shows a sample output for this command:

```
clus1::>> security anti-ransomware volume space show
          Space Used By Space Used By Total Space Snapshot
Vserver  Volume      Snapshot      logs      Used      Copies
-----  -
vs1      vol1              308KB      8B        308.0KB      2
```

# security anti-ransomware volume workload-behavior clear-surge

Clear the observed surge values on a volume

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege

level.

## Description

The `security anti-ransomware volume workload-behavior clear-surge` command clears the observed surge values.

## Parameters

### `-vserver <vserver name>` - Vserver Name

This parameter specifies the Vserver on which the volume is located.

### `-volume <volume name>` - Volume Name

This parameter specifies the name of the volume on which anti-ransomware feature is enabled.

## Examples

```
cluster1::> security anti-ransomware volume workload-behavior show -vserver vs1
-volume vol1
                Vserver                : vs1
                Volume                  : vol1
                File Extensions Observed : .txt, .exe, .pdf, .img
                Number of File Extensions Observed : 4
Historical Statistics
  High Entropy Data Write Percentage      : 50
  High Entropy Data Write Peak Rate (KB/Minute) : 50
  File Create Peak Rate (per Minute)      : 100
  File Delete Peak Rate (per Minute)      : 100
  File Rename Peak Rate (per Minute)      : 100

## security anti-ransomware volume workload-behavior show

Display information about the volume's workload-behavior learnt by the analytics algorithm

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

### Description

This **security anti-ransomware volume workload-behavior show** displays the workload characteristics observed during anti-ransomware monitoring.

### Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ [-instance ] ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**-vserver <Vserver Name> - Vserver Name**

This parameter specifies the Vserver of the anti-ransomware enabled volume.

**-volume <volume name> - Volume Name**

This parameter specifies the anti-ransomware enabled volume for which the workload behavior

details are displayed.

**[-file-extensions-included <text>,...] - List of File Extensions Observed**

This parameter displays the list of file extensions observed during anti-ransomware monitoring.

**[-total-file-extensions-included <integer>] - Number of File Extensions Observed**

This parameter displays the number of file extensions observed during anti-ransomware monitoring.

**[-high-entropy-data-write-peak-percent <integer>] - High Entropy Data Write Peak Percentage**

This parameter displays the peak historical high entropy data write percentage of the incoming data.

**[-high-entropy-data-write-peak-rate <integer>] - High Entropy Data Write Peak Rate (KB/minute)**

This parameter displays the peak historical high entropy data write rate.

**[-file-create-peak-rate <integer>] - File Create Peak Rate per Minute**

This parameter displays the peak historical rate of file create operations in the volume.

**[-file-rename-peak-rate <integer>] - File Rename Peak Rate per Minute**

This parameter displays the peak historical rate of file rename operations in the volume.

**[-file-delete-peak-rate <integer>] - File Delete Peak Rate per Minute**

This parameter displays the peak historical rate of file delete operations in the volume.

**[-surge-timeline <MM/DD/YYYY HH:MM:SS>] - Surge Timeline**

This parameter displays the timeline where a surge was observed in the workload characteristics compared to the historically learnt characteristics.

**[-surge-high-entropy-data-write-peak-percent <integer>] - High Entropy Data Write Percentage During Surge**

This parameter displays the peak percentage value of high entropy data write in the incoming data when the surge was observed.

**[-surge-high-entropy-data-write-peak-rate <integer>] - High Entropy Data-write Peak Rate Surge (KB/minute)**

This parameter displays the peak rate of high entropy data write when the surge was observed.

**[-surge-file-create-peak-rate <integer>] - File Create Peak Rate (per Minute) During Surge**

This parameter displays the surge in the peak rate of file create operations.

**[-surge-file-delete-peak-rate <integer>] - File Delete Peak Rate (per Minute) During Surge**

This parameter displays the surge in the peak rate of file delete operations.

**[-surge-file-rename-peak-rate <integer>] - File Rename Peak Rate (per Minute) During Surge**

This parameter displays the surge in the peak rate of file rename operations.

**[-attack-file-extensions-observed <text>,...] - File Extensions Observed During Attack**

This parameter displays the list of file types observed during a suspected ransomware attack.

**[-attack-file-extensions-observed-counts <integer>,...] - Number of File Extensions Observed During Attack**

This parameter displays the count of various file types observed during a suspected ransomware attack.

## Examples

The following example shows sample output for this command:

```
cluster1::> security anti-ransomware volume workload-behavior show -vserver vs1
-volume vol1
                Vserver                : vs1
                Volume                  : vol1
                File Extensions Observed : .ext1, .ext2, .ext3
                Number of File Extensions Observed : 3
Historical Statistics
  High Entropy Data Write Percentage      : 50
  High Entropy Data Write Peak Rate (KB/Minute) : 50
  File Create Peak Rate (per Minute)      : 100
  File Delete Peak Rate (per Minute)      : 100
  File Rename Peak Rate (per Minute)      : 100
Surge Observed
  Surge Timeline                          : 1/1/2022 01:01:01

  High Entropy Data Write Peak Rate (KB/Minute) : 200
  File Create Peak Rate (per Minute)      : 200
  File Delete Peak Rate (per Minute)      : 200
  File Rename Peak Rate (per Minute)      : 200
  Newly Observed File Extensions          : .uk1,.uk2,.uk3
  Number of Newly Observed File Extensions : 1, 2, 3
```

# security anti-ransomware volume workload-behavior update-baseline-from-surge

Set the observed surge values as the new baseline on a volume

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `security anti-ransomware volume workload-behavior update-baseline-from-surge` command sets

the observed surge value as new baseline.

## Parameters

### **-vserver <vserver name> - Vserver Name**

This parameter specifies the Vserver on which the volume is located.

### **-volume <volume name> - Volume Name**

This parameter specifies the name of the volume on which anti-ransomware feature is enabled.

## Examples

```
cluster1::> security anti-ransomware volume workload-behavior show -vserver vs1
-volume vol1
```

```

                Vserver                : vs1
                Volume                  : vol1
                File Extensions Observed : .txt, .exe, .pdf, .img
                Number of File Extensions Observed : 4

```

#### Historical Statistics

```

High Entropy Data Write Percentage      : 50
High Entropy Data Write Peak Rate (KB/Minute) : 50
File Create Peak Rate (per Minute)      : 100
File Delete Peak Rate (per Minute)      : 100
File Rename Peak Rate (per Minute)      : 100

```

#### Surge Observed

## security audit modify

Set administrative audit logging settings

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The `security audit modify` command modifies the following audit-logging settings for the management interface:

- Whether get requests for the CLI are audited
- Whether get requests for the Data ONTAP API (ONTAPI) are audited

### Parameters

#### `[-cliget {on|off}]` - Enable Auditing of CLI Get Operations

This specifies whether get requests for the CLI are audited. The default setting is **off**.

#### `[-httpget {on|off}]` - Enable Auditing of HTTP Get Operations

This specifies whether get requests for the web (HTTP) interface are audited. The default setting is **off**.

#### `[-ontapiget {on|off}]` - Enable Auditing of Data ONTAP API Get Operations

This specifies whether get requests for the Data ONTAP API (ONTAPI) interface are audited. The default setting is **off**.

### Examples

The following example turns off auditing of get requests for the CLI interface:

```
cluster1::> security audit modify -cliget off
```

# security audit show

Show administrative audit logging settings

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **security audit show** command displays the following audit-logging settings for the management interface:

- Whether get requests for the CLI are audited
- Whether get requests for the web (HTTP) interface are audited
- Whether get requests for the Data ONTAP API (ONTAPI) are audited

Audit log entries are written to the 'audit' log, viewable via the 'security audit log show' command.

## Examples

The following example displays the audit-logging settings for the management interface:

```
cluster1::> security audit show
      Auditing State for
      Operation Get Requests
      -----
      CLI off
      HTTP off
      ONTAPI off
```

# security audit log show

Display audit entries merged from multiple nodes in the cluster

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **security audit log show** command displays cluster-wide audit log messages. Messages from each node are interleaved in chronological order.

## Parameters

{ [-fields <fieldname>, ...]

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the

---

specified field or fields. You can use '-fields ?' to display the fields to specify.

**[ [-detail ]**

This display option shows the individual fields of the audit record.

**[ [-instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-timestamp <Date>] - Log Entry Timestamp**

Selects the entries that match the specified input for timestamp. This will be in a human-readable format <day> <month> <day of month> <hour>:<min>:<sec> <year> in the local timezone.

**[-node {<nodename>|local}] - Node**

Selects the entries that match the specified input for node.

**[-entry <text>] - Log Message Entry**

Selects the entries that match the specified input for entry.

**[-session-id <text>] - Session ID**

This is the "session id" for this audit record. Each ssh/console session is assigned a unique session ID. Each ZAPI/HTTP/SNMP request is assigned a unique session ID.

**[-command-id <text>] - Command ID**

This is useful with ssh/console sessions. Each command in a session is assigned a unique command ID. Each ZAPI/HTTP/SNMP request does not have a command ID.

**[-application <text>] - Protocol**

This is the application used to connect to the cluster. Possible values include the following: internal, console, ssh, http, ontapi, snmp, rsh, telnet, service-processor

**[-location <text>] - Remote user location**

The remote IP address or remote access point.

**[-vserver <text>] - Vserver name**

Storage Virtual Machine name

**[-username <text>] - Username**

Username

**[-input <text>] - Command being executed**

The operation being attempted

**[-state {Pending|Success|Error}] - State of this audit request**

State of this request

**[-message <text>] - Additional information and/or error message**

Additional information which may be error or informative message.

## Examples

The following example displays specific fields based on a custom query:

```
cluster1::> security audit log show -fields application, location, state, input,
message -location 10.60.* -state Error|Success -input v*|st* -timestamp >"Jul 10
12:00:00 2020"
timestamp                node  application location    input
state  message
-----
"Fri Jul 17 11:32:44 2020" node1 ssh          10.60.250.79 storage aggregate create
test -diskcount 5 Success -
"Fri Jul 17 11:36:47 2020" node1 ssh          10.60.250.79 vserver create vs1
Success -
"Fri Jul 17 11:37:33 2020" node1 ssh          10.60.250.79 volume create vol1
Error One of the following parameters is required: -aggregate, -aggr-list, -auto
-provision-as
"Fri Jul 17 11:38:08 2020" node1 ssh          10.60.250.79 volume create vol1
-aggregate test          Success -
Some more examples for -timestamp usage:
cluster1::> security audit log show -timestamp "Mon Jan 03 18:37:05 2022"
Time                      Node           Audit Message
-----
Mon Jan 03 18:37:05 2022  node1
                                [kern_audit:info:988] mlogd: started

cluster1::> security audit log show -timestamp Mon Jan 03 *
Time                      Node           Audit Message
-----
Mon Jan 03 18:37:05 2022  node1
                                [kern_audit:info:988] mlogd: started
Mon Jan 03 18:37:06 2022  node2
                                [kern_audit:info:988] mlogd: started
Mon Jan 03 18:41:25 2022  node1
                                [kern_audit:info:977] mlogd: started
Mon Jan 03 18:41:25 2022  node2
                                [kern_audit:info:977] mlogd: started

cluster1::> security audit log show -timestamp Mon Jan 03 18:37*
Time                      Node           Audit Message
-----

# security certificate create

## Create and Install a Self-Signed Digital Certificate

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **security certificate create** command creates and installs a self-signed digital certificate, which can be used for server authentication, for signing other certificates by acting as a certificate authority (CA), or for Data ONTAP as an SSL client. The certificate function is selected by the **-type** field. Self-signed digital certificates are not as secure as certificates signed by a CA. Therefore, they are not recommended in a production environment.

## Parameters

**-vserver <Vserver Name> - Name of Vserver**

This specifies the name of the Vserver on which the certificate will exist.

**-common-name <FQDN or Custom Common Name> - FQDN or Custom Common Name**

This specifies the desired certificate name as a fully qualified domain name (FQDN) or custom common name or the name of a person. The supported characters, which are a subset of the ASCII character set, are as follows:

- Letters a through z, A through Z
- Numbers 0 through 9
- Asterisk (\*), period (.), underscore (\_) and hyphen (-)

The common name must not start or end with a "-" or a ".". The maximum length is 253 characters.

**-type <type of certificate> - Type of Certificate**

This specifies the certificate type. Valid values are the following:

- **server** - creates and installs a self-signed digital certificate and intermediate certificates to be used for server authentication
- **root-ca** - creates and installs a self-signed digital certificate to sign other certificates by acting as a certificate authority (CA)
- **client** - includes a self-signed digital certificate and private key to be used for Data ONTAP as an SSL client

**[-subtype <kmip-cert>] - (DEPRECATED)-Certificate Subtype**

This parameter has been deprecated in ONTAP 9.6 and may be removed in a future release of Data ONTAP.

This specifies a certificate subtype. This optional parameter can have an empty value (the default). The only valid value is as follows:

- **kmip-cert** - this is a Key Management Interoperability Protocol (KMIP) certificate

#### **[-cert-name <text>] - Unique Certificate Name**

This specifies the system's internal identifier for the certificate. It must be unique within a Vserver. If not provided, it is automatically generated by the system.

#### **-size <size of requested certificate in bits> - Size of Requested Certificate in Bits**

This specifies the number of bits in the private key. The larger the value, the more secure is the key. The default is 2048. Possible values include **512** , **1024** , **1536** , **2048** and **3072** when the "FIPS Mode" in "security config" is false. When the "FIPS Mode" is true, the possible values are **2048** and **3072** .

#### **-country <text> - Country Name**

This specifies the country where the Vserver resides. The country name is a two-letter code. The default is US. Here is the list of country codes:

<u>Country</u>	<u>Codes</u>	[ <a href="http://www.iso.org/iso/country_codes/iso_3166_code_lists/country_names_and_code_elements.htm">http://www.iso.org/iso/country_codes/iso_3166_code_lists/country_names_and_code_elements.htm</a> ]
----------------	--------------	---

#### **-state <text> - State or Province Name**

This specifies the state or province where the Vserver resides.

#### **-locality <text> - Locality Name**

This specifies the locality where the Vserver resides. For example, the name of a city.

#### **-organization <text> - Organization Name**

This specifies the organization where the Vserver resides. For example, the name of a company.

#### **-unit <text> - Organization Unit**

This specifies the unit where the Vserver resides. For example, the name of a section or a department within a company.

#### **-email-addr <mail address> - Contact Administrator's Email Address**

This specifies the email address of the contact administrator for the Vserver.

#### **-expire-days <integer> - Number of Days until Expiration**

This specifies the number of days until the certificate expires. The default value is 365 days. Possible values are between **1** and **3652** .

#### **-protocol <protocol> - Protocol**

This specifies the protocol type. This parameter currently supports only the SSL protocol type. The default is SSL.

#### **-hash-function <hashing function> - Hashing Function**

This specifies the cryptographic hashing function for signing the certificate. The default is

SHA256. Possible values include **SHA256** , **SHA224** , **SHA384** and **SHA512** .

## Examples

This example creates a server type, self-signed digital certificate for a Vserver named vs0 at a company whose custom common name is **www.example.com** and whose Vserver name is vs0.

```
cluster1::> security certificate create -vserver vs0 -common-name www.example.com
-type server
```

This example creates a root-ca type, self-signed digital certificate with a 2048-bit private key generated by the SHA256 hashing function that will expire in 365 days for a Vserver named vs0 for use by the Software group in IT at a company whose custom common name is **www.example.com** , located in Sunnyvale, California, USA. The email address of the contact administrator who manages the Vserver is **web@example.com** .

```
cluster1::> security certificate create -vserver vs0 -common-name www.example.com
-type root-ca -size 2048 -country US -state California -locality Sunnyvale
-organization IT -unit Software -email-addr web@example.com -expire-days 365 -hash
-function SHA256
```

This example creates a client type of self-signed digital certificate for a Vserver named vs0 at a company that uses Data ONTAP as an SSL client. The company's custom common name is **www.example.com** and its Vserver name is vs0.

```
cluster1::> security certificate create -vserver vs0 -common-name www.example.com
-type client -size 2048 -country US -state California -locality Sunnyvale
-organization IT -unit Software -email-addr web@example.com -expire-days 365 -hash
-function SHA256
```

## security certificate delete

Delete an Installed Digital Certificate

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command deletes an installed digital security certificate.

## Parameters

### **-vserver <Vserver Name> - Name of Vserver**

This specifies the Vserver that contains the certificate.

### **-common-name <FQDN or Custom Common Name> - FQDN or Custom Common Name**

This specifies the desired certificate name as a fully qualified domain name (FQDN) or custom common name or the name of a person. The supported characters, which are a subset of the ASCII character set, are as follows:

- Letters a through z, A through Z
- Numbers 0 through 9
- Asterisk (\*), period (.), underscore (\_) and hyphen (-)

The common name must not start or end with a "-" or a ".". The maximum length is 253 characters.

### **[-serial <text>] - Serial Number of Certificate**

This specifies the certificate serial number.

### **-ca <text> - Certificate Authority**

This specifies the certificate authority (CA).

### **-type <type of certificate> - Type of Certificate**

This specifies the certificate type. Valid values are the following:

- **server** - includes server certificates and intermediate certificates
- **root-ca** - includes a self-signed digital certificate to sign other certificates by acting as a certificate authority (CA)
- **client-ca** - includes the public key certificate for the root CA of the SSL client. If this client-ca certificate is created as part of a root-ca, it will be deleted along with the corresponding deletion of the root-ca.
- **server-ca** - includes the public key certificate for the root CA of the SSL server to which Data ONTAP is a client. If this server-ca certificate is created as part of a root-ca, it will be deleted along with the corresponding deletion of the root-ca.
- **client** - includes a public key certificate and private key to be used for Data ONTAP as an SSL client

### **[-subtype <kmip-cert>] - (DEPRECATED)-Certificate Subtype**

This parameter has been deprecated in ONTAP 9.6 and may be removed in a future release of Data ONTAP.

This specifies a certificate subtype. This optional parameter can have an empty value (the default). The only valid value is as follows:

- **kmip-cert** - this is a Key Management Interoperability Protocol (KMIP) certificate

**[-cert-name <text>] - Unique Certificate Name**

This specifies the system's internal identifier for the certificate. It is unique within a Vserver.

## Examples

This example deletes a root-ca type digital certificate for a Vserver named vs0 in a company named **www.example.com** with serial number 4F57D3D1.

```
cluster1::> security certificate delete -vserver vs0 -common-name www.example.com -ca
www.example.com -type root-ca -serial 4F57D3D1
```

# security certificate generate-csr

## Generate a Digital Certificate Signing Request

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command generates a digital certificate signing request and displays it on the console. A certificate signing request (CSR or certification request) is a message sent to a certificate authority (CA) to apply for a digital identity certificate.

## Parameters

**[-common-name <text>] - FQDN or Custom Common Name**

This specifies the desired certificate name as a fully qualified domain name (FQDN) or custom common name or the name of a person. The supported characters, which are a subset of the ASCII character set, are as follows:

- Letters a through z, A through Z
- Numbers 0 through 9
- Asterisk (\*), period (.), underscore (\_) and hyphen (-)

The common name must not start or end with a "-" or a ".". The maximum length is 253 characters.

**{ [-size <size of requested certificate in bits>] - (DEPRECATED)-Size of Requested Certificate in Bits**

This specifies the number of bits in the private key. A larger size value provides for a more secure key. The default is 2048. Possible values include **512** , **1024** , **1536** , and **2048** .

This parameter has been deprecated in ONTAP 9.8 and may be removed in future releases of Data ONTAP. Use the security-strength parameter instead.

**[ -security-strength <bits of security strength> ] - Security Strength in Bits }**

Use this parameter to specify the minimum security strength of the certificate in bits. The security bits mapping to RSA and ECDSA key length, in bits, are as follows:

Size	RSA Key Length	Elliptic Curve Key Length
112	2048	224
128	3072	256
192	4096	384

Note: FIPS supported values are restricted to 112 and 128.

**[ -algorithm <Asymmetric key generation algorithm> ] - Asymmetric Encryption Algorithm**

Use this parameter to specify the asymmetric encryption algorithm to use for generating the public/private key for the certificate signing request. Algorithm values can be RSA or EC. Default value is RSA.

**[ -country <text> ] - Country Name**

This specifies the country where the Vserver resides. The country name is a two-letter code. The default is US. Here is the list of country codes:

Country \_\_\_\_\_ Codes [[http://www.iso.org/iso/country\\_codes/iso\\_3166\\_code\\_lists/country\\_names\\_and\\_code\\_elements.htm](http://www.iso.org/iso/country_codes/iso_3166_code_lists/country_names_and_code_elements.htm)]

**[ -state <text> ] - State or Province Name**

This specifies the state or province where the Vserver resides.

**[ -locality <text> ] - Locality Name**

This specifies the locality where the Vserver resides. For example, the name of a city.

**[ -organization <text> ] - Organization Name**

This specifies the organization where the Vserver resides. For example, the name of a company.

**[ -unit <text> ] - Organization Unit**

This specifies the unit where the Vserver resides. For example, the name of a section or a department within a company.

**[ -email-addr <mail address> ] - Contact Administrator's Email Address**

This specifies the email address of the contact administrator for the Vserver.

**[ -hash-function <hashing function> ] - Hashing Function**

This specifies the cryptographic hashing function for signing the certificate. The default is SHA256. Possible values include **SHA224** , **SHA256** , **SHA384** , and **SHA512** .

**[ -key-usage <Certificate key usage extension>, ... ] - Key Usage Extension**

Use this parameter to specify the key usage extension values. The default values are: **digitalSignature** , **keyEncipherment** . Possible values include:

- digitalSignature
- nonRepudiation
- keyEncipherment
- dataEncipherment
- keyAgreement
- keyCertSigning
- cRLSigning
- encipherOnly
- decipherOnly

#### **[-extended-key-usage <Certificate extKeyUsage extension>,...]** - Extended Key Usage Extension

Use this parameter to specify the extended key usage extension values. The default values are: **serverAuth** , **clientAuth** . Possible values include:

- serverAuth
- clientAuth
- codeSigning
- emailProtection
- timeStamping
- OCSPSigning

#### **[-rfc822-name <mail address>,...]** - Email Address SAN

Use this parameter to specify the Subject Alternate Name extension - a list of rfc822-names (email addresses).

#### **[-uri <text>,...]** - URI SAN

Use this parameter to specify the Subject Alternate Name extension - a list of URIs.

#### **[-dns-name <text>,...]** - DNS Name SAN

Use this parameter to specify the Subject Alternate Name extension - a list of DNS names.

#### **[-ipaddr <IP Address>,...]** - IP Address SAN

Use this parameter to specify the Subject Alternate Name extension - a list of IP addresses.

## Examples

This example creates a certificate-signing request with a 2048-bit RSA private key generated by the SHA256 hashing function for use by the Engineering group in IT at a company whose custom common name is **www.example.com** , located in Durham, NC, USA. The email address of the contact administrator who manages the Vserver is **web@example.com** The request also specifies the subject alternative names, key-usage and extended-key-usage extensions.

```
cluster-1::> security certificate generate-csr -common-name www.example.com -algorithm
```

```
RSA -hash-function SHA256 -security-strength 128 -key-usage
critical,digitalSignature,keyEncipherment -extended-key-usage serverAuth,clientAuth
-country US -state NC -locality Durham -organization IT -unit Engineering -email-addr
web@example.com -rfc822-name example@example.com -dns-name shop.example.com ,
store.example.com
```

## security certificate install

### Install a Digital Certificate

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

### Description

The **security certificate install** command installs digital security certificates signed by a certificate authority (CA) and the public key certificate of the root CA. Digital security certificates also include the intermediate certificates to construct the chain for server certificates (the server type), client-side root CA certificates (the client-ca type), or server-side root CA certificates (the server-ca type). with FIPS enabled, the following restrictions apply to the certificate getting installed. server/client/server-ca/client-ca: Key size >= 2048,server/client: Hash function (No MD-5, No SHA-1),server-ca/client-ca: (Intermediate CA), Hash Function (No MD-5, No SHA-1), server-ca/client-ca: (Root CA), Hash Function (No MD-5)

## Parameters

### -vserver <Vserver Name> - Name of Vserver

This specifies the Vserver that contains the certificate.

### -type <type of certificate> - Type of Certificate

This specifies the certificate type. Valid values are the following:

- **server** - includes server certificates and intermediate certificates.
- **client-ca** - includes the public key certificate for the root CA of the SSL client
- **server-ca** - includes the public key certificate for the root CA of the SSL server to which Data ONTAP is a client
- **client** - includes a self-signed or CA-signed digital certificate and private key to be used for Data ONTAP as an SSL client

### [-subtype <kmip-cert>] - (DEPRECATED)-Certificate Subtype

This parameter has been deprecated in ONTAP 9.6 and may be removed in a future release of Data ONTAP.

This specifies a certificate subtype. This optional parameter can have an empty value (the default). The only valid value is as follows:

- **kmip-cert** - this is a Key Management Interoperability Protocol (KMIP) certificate

### [-cert-name <text>] - Unique Certificate Name

This specifies the system's internal identifier for the certificate. It must be unique within a Vserver. If not provided, it is automatically generated by the system.

## Examples

This example installs a CA-signed certificate (along with intermediate certificates) for a Vserver named vs0.

```
cluster1::> security certificate install -vserver vs0 -type server
Please enter Certificate: Press <Enter> when done

## security certificate print

Display the contents of a certificate

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

### Description

This command displays the details of either an installed certificate or by reading a certificate from user input.

### Parameters

**-vserver <Vserver Name> - Vserver Name**

Use this parameter to specify the Vserver that has the certificate installed.

**{ [-cert-name <text>] - Installed Certificate Name**

Use this parameter to specify the unique name of the installed certificate to read and display.

**| [-cert-uuid <UUID>] - Installed Certificate UUID }**

Use this parameter to specify the unique UUID of the installed certificate to read and display. With no name or UUID specified, the certificate will read and display from user input.

## Examples

The following example reads and prints the details of the certificate.

```
cluster1::> security certificate print -vserver vs0 -cert-name AAACertificateServices

# security certificate rename

Rename a certificate

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command allows the user to modify the name of an installed digital certificate. This command does not alter the certificate itself.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

This specifies the name of the Vserver on which the certificate exists.

**-cert-name <text> - Existing Certificate Name**

This specifies the current name of the certificate.

**-new-name <text> - New Certificate Name**

This specifies the desired name of the certificate. It must be unique among certificates in the Vserver.

## Examples

```
cluster1::> security certificate rename -vserver vs0 -cert-name AAACertificateServices  
-new-nameAAACertServ
```

# security certificate show-generated

Display ONTAP generated certificates

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command displays information about the Data ONTAP generated digital digital certificates. Some details are displayed only when you use the command with the *-instance* parameter.

## Parameters

{ [-fields <fieldname>, ... ] }

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[ [-instance ] ] }

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-vserver <Vserver Name>] - Name of Vserver**

Selects the Vserver whose digital certificates you want to display.

**[-common-name <FQDN or Custom Common Name>] - FQDN or Custom Common Name**

Selects the certificates that match this parameter value.

**[-serial <text>] - Serial Number of Certificate**

Selects the certificates that match this parameter value.

**[-ca <text>] - Certificate Authority**

Selects the certificates that match this parameter value.

**[-type <type of certificate>] - Type of Certificate**

Selects the certificates that match this parameter value.

**[-subtype <kmip-cert>] - (DEPRECATED)-Certificate Subtype**

This parameter has been deprecated in ONTAP 9.6 and may be removed in a future release of Data ONTAP.

Selects the certificate subtype that matches the specified value. The valid values are as follows:

- **kmip-cert** - this is a Key Management Interoperability Protocol (KMIP) certificate

**[-cert-name <text>] - Unique Certificate Name**

This specifies the system's internal identifier for the certificate. It is unique within a Vserver.

**[-size <size of requested certificate in bits>] - Size of Requested Certificate in Bits**

Selects the certificates that match this parameter value.

**[-start <Date>] - Certificate Start Date**

Selects the certificates that match this parameter value.

**[-expiration <Date>] - Certificate Expiration Date**

Selects the certificates that match this parameter value.

**[-public-cert <certificate>] - Public Key Certificate**

Selects the certificates that match this parameter value.

**[-country <text>] - Country Name**

Selects the certificates that match this parameter value.

**[-state <text>] - State or Province Name**

Selects the certificates that match this parameter value.

**[-locality <text>] - Locality Name**

Selects the certificates that match this parameter value.

**[-organization <text>] - Organization Name**

Selects the certificates that match this parameter value.

**[-unit <text>] - Organization Unit**

Selects the certificates that match this parameter value.

**[-email-addr <mail address>] - Contact Administrator's Email Address**

Selects the certificates that match this parameter value.

**[-protocol <protocol>] - Protocol**

Selects the certificates that match this parameter value.

**[-hash-function <hashing function>] - Hashing Function**

Selects the certificates that match this parameter value.

**[-self-signed {true|false}] - Self-Signed Certificate**

Selects the certificates that match this parameter value.

**[-is-root {true|false}] - Is Root CA Certificate?**

Selects the certificates that match this parameter value.

**[-authority-key-identifier <text>] - Authority Key Identifier**

Selects the certificates that match this parameter value.

**[-subject-key-identifier <text>] - Subject Key Identifier**

Selects the certificates that match this parameter value.

## Examples

The examples below display information about Data ONTAP generated digital certificates.

```
cluster1::> security certificate show-generated
```

Vserver	Serial Number	Certificate Name	Type
-----	-----	-----	-----

```
vs0          4F4E4D7B          www.example.com          server
Certificate Authority: www.example.com
Expiration Date: Thu Feb 28 16:08:28 2013
```

```

## security certificate show-truststore

Display default truststore certificates

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command displays information about the default CA certificates that come pre-installed with Data ONTAP. Some details are displayed only when you use the command with the `-instance` parameter.

## Parameters

**{ [-fields <fieldname>,...]**

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

**[-instance ]}**

If you specify the `-instance` parameter, the command displays detailed information about all fields.

**[-vserver <Vserver Name>] - Name of Vserver**

Selects the Vserver whose digital certificates you want to display.

**[-common-name <FQDN or Custom Common Name>] - FQDN or Custom Common Name**

Selects the certificates that match this parameter value.

**[-serial <text>] - Serial Number of Certificate**

Selects the certificates that match this parameter value.

**[-ca <text>] - Certificate Authority**

Selects the certificates that match this parameter value.

**[-type <type of certificate>] - Type of Certificate**

Selects the certificates that match this parameter value.

**[-subtype <kmip-cert>] - (DEPRECATED)-Certificate Subtype**

This parameter has been deprecated in ONTAP 9.6 and may be removed in a future release of Data ONTAP.

Selects the certificate subtype that matches the specified value. The valid values are as follows:

- **kmip-cert** - this is a Key Management Interoperability Protocol (KMIP) certificate

**[-cert-name <text>] - Unique Certificate Name**

This specifies the system's internal identifier for the certificate. It is unique within a Vserver.

**[-size <size of requested certificate in bits>] - Size of Requested Certificate in Bits**

Selects the certificates that match this parameter value.

**[-start <Date>] - Certificate Start Date**

Selects the certificates that match this parameter value.

**[-expiration <Date>] - Certificate Expiration Date**

Selects the certificates that match this parameter value.

**[-public-cert <certificate>] - Public Key Certificate**

Selects the certificates that match this parameter value.

**[-country <text>] - Country Name**

Selects the certificates that match this parameter value.

**[-state <text>] - State or Province Name**

Selects the certificates that match this parameter value.

**[-locality <text>] - Locality Name**

Selects the certificates that match this parameter value.

**[-organization <text>] - Organization Name**

Selects the certificates that match this parameter value.

**[-unit <text>] - Organization Unit**

Selects the certificates that match this parameter value.

**[-email-addr <mail address>] - Contact Administrator's Email Address**

Selects the certificates that match this parameter value.

**[-protocol <protocol>] - Protocol**

Selects the certificates that match this parameter value.

**[-hash-function <hashing function>] - Hashing Function**

Selects the certificates that match this parameter value.

**[-self-signed {true|false}] - Self-Signed Certificate**

Selects the certificates that match this parameter value.

**[-is-root {true|false}] - Is Root CA Certificate?**

Selects the certificates that match this parameter value.

**[-authority-key-identifier <text>] - Authority Key Identifier**

Selects the certificates that match this parameter value.

**[-subject-key-identifier <text>] - Subject Key Identifier**

Selects the certificates that match this parameter value.

## Examples

The examples below display information about the pre-installed truststore digital certificates.

```
cluster1::> security certificate show-truststore

# security certificate show-user-installed

Display user installed certificates

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command displays information about the user installed digital certificates. Some details are displayed only when you use the command with the `-instance` parameter. In systems upgraded, existing Data ONTAP generated certificates will also be shown as part of this command.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

**[ -instance ] }**

If you specify the `-instance` parameter, the command displays detailed information about all fields.

**[ -vserver <Vserver Name> ] - Name of Vserver**

Selects the Vserver whose digital certificates you want to display.

**[ -common-name <FQDN or Custom Common Name> ] - FQDN or Custom Common Name**

Selects the certificates that match this parameter value.

**[ -serial <text> ] - Serial Number of Certificate**

Selects the certificates that match this parameter value.

**[ -ca <text> ] - Certificate Authority**

Selects the certificates that match this parameter value.

**[ -type <type of certificate> ] - Type of Certificate**

Selects the certificates that match this parameter value.

**[ -subtype <kmip-cert> ] - (DEPRECATED)-Certificate Subtype**

This parameter has been deprecated in ONTAP 9.6 and may be removed in a future release of Data ONTAP.

Selects the certificate subtype that matches the specified value. The valid values are as follows:

- **kmip-cert** - this is a Key Management Interoperability Protocol (KMIP) certificate

**[-cert-name <text>] - Unique Certificate Name**

This specifies the system's internal identifier for the certificate. It is unique within a Vserver.

**[-size <size of requested certificate in bits>] - Size of Requested Certificate in Bits**

Selects the certificates that match this parameter value.

**[-start <Date>] - Certificate Start Date**

Selects the certificates that match this parameter value.

**[-expiration <Date>] - Certificate Expiration Date**

Selects the certificates that match this parameter value.

**[-public-cert <certificate>] - Public Key Certificate**

Selects the certificates that match this parameter value.

**[-country <text>] - Country Name**

Selects the certificates that match this parameter value.

**[-state <text>] - State or Province Name**

Selects the certificates that match this parameter value.

**[-locality <text>] - Locality Name**

Selects the certificates that match this parameter value.

**[-organization <text>] - Organization Name**

Selects the certificates that match this parameter value.

**[-unit <text>] - Organization Unit**

Selects the certificates that match this parameter value.

**[-email-addr <mail address>] - Contact Administrator's Email Address**

Selects the certificates that match this parameter value.

**[-protocol <protocol>] - Protocol**

Selects the certificates that match this parameter value.

**[-hash-function <hashing function>] - Hashing Function**

Selects the certificates that match this parameter value.

**[-self-signed {true|false}] - Self-Signed Certificate**

Selects the certificates that match this parameter value.

**[-is-root {true|false}] - Is Root CA Certificate?**

Selects the certificates that match this parameter value.

**[-authority-key-identifier <text>] - Authority Key Identifier**

Selects the certificates that match this parameter value.

**[-subject-key-identifier <text>] - Subject Key Identifier**

Selects the certificates that match this parameter value.

## Examples

The examples below display information about user installed digital certificates.

```
cluster1::> security certificate show-user-installed

# security certificate show

## Display Installed Digital Certificates

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command displays information about the installed digital certificates. Some details are displayed only when you use the command with the `-instance` parameter.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

**[ -instance ] }**

If you specify the `-instance` parameter, the command displays detailed information about all fields.

**[ -vserver <Vserver Name> ] - Name of Vserver**

Selects the Vserver whose digital certificates you want to display.

**[ -common-name <FQDN or Custom Common Name> ] - FQDN or Custom Common Name**

Selects the certificates that match this parameter value.

**[ -serial <text> ] - Serial Number of Certificate**

Selects the certificates that match this parameter value.

**[ -ca <text> ] - Certificate Authority**

Selects the certificates that match this parameter value.

**[ -type <type of certificate> ] - Type of Certificate**

Selects the certificates that match this parameter value.

**[ -subtype <kmip-cert> ] - (DEPRECATED)-Certificate Subtype**

This parameter has been deprecated in ONTAP 9.6 and may be removed in a future release of Data ONTAP.

Selects the certificate subtype that matches the specified value. The valid values are as follows:

- **kmip-cert** - this is a Key Management Interoperability Protocol (KMIP) certificate

**[-cert-name <text>] - Unique Certificate Name**

This specifies the system's internal identifier for the certificate. It is unique within a Vserver.

**[-size <size of requested certificate in bits>] - Size of Requested Certificate in Bits**

Selects the certificates that match this parameter value.

**[-start <Date>] - Certificate Start Date**

Selects the certificates that match this parameter value.

**[-expiration <Date>] - Certificate Expiration Date**

Selects the certificates that match this parameter value.

**[-public-cert <certificate>] - Public Key Certificate**

Selects the certificates that match this parameter value.

**[-country <text>] - Country Name**

Selects the certificates that match this parameter value.

**[-state <text>] - State or Province Name**

Selects the certificates that match this parameter value.

**[-locality <text>] - Locality Name**

Selects the certificates that match this parameter value.

**[-organization <text>] - Organization Name**

Selects the certificates that match this parameter value.

**[-unit <text>] - Organization Unit**

Selects the certificates that match this parameter value.

**[-email-addr <mail address>] - Contact Administrator's Email Address**

Selects the certificates that match this parameter value.

**[-protocol <protocol>] - Protocol**

Selects the certificates that match this parameter value.

**[-hash-function <hashing function>] - Hashing Function**

Selects the certificates that match this parameter value.

**[-self-signed {true|false}] - Self-Signed Certificate**

Selects the certificates that match this parameter value.

**[-is-root {true|false}] - Is Root CA Certificate?**

Selects the certificates that match this parameter value.

**[-authority-key-identifier <text>] - Authority Key Identifier**

Selects the certificates that match this parameter value.

**[-subject-key-identifier <text>] - Subject Key Identifier**

Selects the certificates that match this parameter value.

## Examples

The examples below display information about digital certificates.

```
cluster1::> security certificate show

# security certificate sign

## Sign a Digital Certificate using Self-Signed Root CA

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command signs a digital certificate signing request and generates a certificate using a Self-Signed Root CA certificate in either PEM or PKCS12 format. You can use the [security certificate generate-csr](#) command to generate a digital certificate signing request.

## Parameters

### **-vserver <Vserver Name> - Name of Vserver**

This specifies the name of the Vserver on which the signed certificate will exist.

### **-ca <text> - Certificate Authority to Sign**

This specifies the name of the Certificate Authority that will sign the certificate.

### **-ca-serial <text> - Serial Number of CA Certificate**

This specifies the serial number of the Certificate Authority that will sign the certificate.

### **[-expire-days <integer>] - Number of Days until Expiration**

This specifies the number of days until the signed certificate expires. The default value is 365 days. Possible values are between **1** and **3652**.

### **[-format <certificate format>] - Certificate Format**

This specifies the format of signed certificate. The default value is PEM. Possible values include **PEM** and **PKCS12**.

### **[-destination {(ftp|http|https)://(hostname|IPv4 Address|['IPv6 Address'])...}] - Where to Send File**

This specifies the destination to upload the signed certificate. This option can only be used when the format is PKCS12.

### **[-hash-function <hashing function>] - Hashing Function**

This specifies the cryptographic hashing function for the self-signed certificate. The default value

is SHA256. Possible values include **SHA224** , **SHA256** , **SHA384** , and **SHA512** .

## Examples

This example signs a digital certificate for a Vserver named vs0 using a Certificate Authority certificate that has a ca of **www.ca.com** and a ca-serial of 4F4EB629 in PEM format using the SHA256 hashing function.

```
cluster1::> security certificate sign -vserver vs0 -ca www.ca.com -ca-serial 4F4EB629
-expire-days 36 -format PEM -hash-function SHA256
```

Please enter Certificate Signing Request(CSR): Press <Enter> when done

# security certificate ca-issued revoke

## Revoke a Digital Certificate

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command revokes a digital certificate signed by a Self-Signed Root CA.

## Parameters

**-vserver <Vserver Name> - Name of Vserver**

This specifies the name of the Vserver on which the certificate is stored.

**-serial <text> - Serial Number of Certificate**

This specifies the serial number of the certificate.

**-ca <text> - Certificate Authority**

This specifies the name of the Certificate Authority whose certificate will be revoked.

**-ca-serial <text> - Serial Number of CA Certificate**

This specifies the serial number of Certificate Authority.

**[-common-name <FQDN or Custom Common Name>] - FQDN or Custom Common Name**

This specifies a fully qualified domain name (FQDN) or custom common name or the name of a person. This field is optional if ca-serial is specified.

## Examples

This example revokes a signed digital certificate for a Vserver named vs0 with serial as 4F5A2DF2 for a Certificate Authority certificate that has a ca of **www.ca.com** and a ca-serial of 4F4EB629.

```
cluster1::> security certificate ca-issued revoke -vserver vs0 -serial 4F5A2DF2 -ca  
www.ca.com -ca-serial 4F4EB629
```

# security certificate ca-issued show

## Display CA-Issued Digital Certificates

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command displays the following information about the digital certificates issued by the self-signed root-ca:

- Vserver
- Serial number of certificate
- FQDN or custom common name or the name of a person
- Serial number of CA certificate
- Status (**active**, **revoked**)
- Certificate Authority
- Expiration date
- Revocation date

To display more details, run the command with the **-instance** parameter. This will add the following

information:

- Country name
- State or province name
- Locality name
- Organization name
- Organization unit
- Contact administrator's email address

## Parameters

**{ [-fields <fieldname>,...]**

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[-instance ]}**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-vserver <Vserver Name>] - Name of Vserver**

Selects the certificates that match this parameter value.

**[-serial <text>] - Serial Number of Certificate**

Selects the certificates that match this parameter value.

**[-ca <text>] - Certificate Authority**

Selects the certificates that match this parameter value.

**[-ca-serial <text>] - Serial Number of CA Certificate**

Selects the certificates that match this parameter value.

**[-common-name <FQDN or Custom Common Name>] - FQDN or Custom Common Name**

Selects the certificates that match this parameter value.

**[-status <status of certificate>] - Status of Certificate**

Selects the certificates that match this parameter value. Possible values include active and revoked.

**[-expiration <Date>] - Certificate Expiration Date**

Selects the certificates that match this parameter value.

**[-revocation <Date>] - Certificate Revocation Date**

Selects the certificates that match this parameter value.

**[-country <text>] - Country Name (2 letter code)**

Selects the certificates that match this parameter value.

**[-state <text>] - State or Province Name (full name)**

Selects the certificates that match this parameter value.

**[-locality <text>] - Locality Name (e.g. city)**

Selects the certificates that match this parameter value.

**[-organization <text>] - Organization Name (e.g. company)**

Selects the certificates that match this parameter value.

**[-unit <text>] - Organization Unit (e.g. section)**

Selects the certificates that match this parameter value.

**[-email-addr <mail address>] - Email Address (Contact Name)**

Selects the certificates that match this parameter value.

## Examples

The examples below display information about CA issued digital certificates.

```
cluster1::> security certificate ca-issued show
Serial Number of
Vserver      Serial Number      Common Name          CA's Certificate Status
-----
vs0          4F5A2C90            example.com          4F4EB629            active
Certificate Authority: vs0.cert
Expiration Date: Sat Apr 14 16:15:13 2012
Revocation Date: -

vs0          4F5A2DF2            example.com          4F4EB629            revoked
Certificate Authority: vs0.cert
Expiration Date: Sat Apr 14 16:21:06 2012
Revocation Date: Fri Mar 09 17:08:30 2012

2 entries were displayed.
```

```
cluster1::> security certificate ca-issued show -instance
Vserver: vs0
Serial Number of Certificate: 4F5A2C90
Certificate Authority: vs0.cert
Serial Number of CA Certificate: 4F4EB629
FQDN or Custom Common Name: example.com
Status of Certificate: active
Certificate Expiration Date: Sat Apr 14 16:15:13 2012
Certificate Revocation Date: -
```

```
Country Name (2 letter code): US
State or Province Name (full name): California
  Locality Name (e.g. city): Sunnyvale
Organization Name (e.g. company): example
Organization Unit (e.g. section): IT
Email Address (Contact Name): web@example.com
```

## security certificate config modify

Modify the certificate management configurations

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

This command modifies the certificate management configuration information for the cluster.

### Parameters

#### **[-min-security-strength <bits of security strength>] - Minimum Security Strength**

Use this parameter to modify the allowed minimum security strength for certificates. The security bits mapping to RSA and ECDSA key length are as follows:

Security Bits	Asymmetric Key Length	Elliptic Curve Key Length
112	2048	224
128	3072	256
192	4096	384

FIPS supported values are restricted to 112 and 128.

+

NOTE: This does not affect root CA certificates.

+

#### **[-expiration-warn-threshold <integer>] - Minimum Days to EMS for Expiring Certificates**

Use this parameter to modify the number of days prior to certificate expiration the system sends a warning EMS event.

### Examples

The following example modifies the minimum security strength allowed for certificates.

```
cluster-1::> security certificate config modify -min-security-strength 192
```

## security certificate config show

Displays the certificate management configurations

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

This command displays the certificate management configuration information for the cluster.

"min-security-strength" - If you specify this parameter, the command displays the minimum allowed security strength for certificates.

"expiration-warn-threshold" - If you specify this parameter, the command displays the minimum number of days before expiration date configured for event management system (EMS) notification of expiring certificates.

### Examples

The following example lists minimum security strength certificate management configuration.

```
cluster-1::> security certificate config show -fields min-security-strength
```

```
Minimum Security Strength
```

```
-----
```

```
112
```

## security certificate truststore check

Initiate a TLS connection and identify the root CA certificate

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

### Description

This command allows the user to check if the node can use the installed set of CA certificates to establish a secure connection with the specified server. If the connection attempt fails, the system reports which expected certificates are missing. If the attempt succeeds, the system displays details of the certificates used.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

Use this parameter to specify the Vserver that needs the connectivity check.

**-server <Hostname and Port> - Server Name**

Use this parameter to specify the server to establish a connection with and look up the required CA certificate.

## Examples

The following example demonstrates a missing CA certificate:

```
cluster1::*> security certificate truststore check -vserver cluster1 -server
example.com:443
```

```
Error: command failed: Missing certificate with subject name: "CN = ExampleRoot, C =
US"
```

The following example demonstrates the required certificate being present:

```
cluster1::*> security certificate truststore check -server example.com:443
```

```
CA certificate with cert-name "ExampleRoot" is already installed in the truststore.
Use "security certificate show -cert-name ExampleRoot" to see the details of the CA
certificate.
```

## security certificate truststore clear

Clear the default root certificates from truststore

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **security certificate truststore clear** command deletes the pre-installed certificates of the type 'server-ca'. If you delete these certificates, some of the applications performing SSL communication can fail.

## Examples

The following example removes the default certificate bundle:

```
cluster1::> security certificate truststore clear
```

# security certificate truststore load

Load the default root certificates to truststore

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `security certificate truststore load` command installs default root certificates in the certificate table of type 'server-ca'. These are the certificates required to validate any incoming server certificate during the SSL handshake process. Note: This command only installs PEM formatted certificates.

## Parameters

**{ [-path <text>] - File to load PEM certificates from**

This specifies the path to the PEM formatted certificate bundle. This optional parameter can have an empty value (the default).

**| [-uri <text>] - URL to download PEM certificates from }**

This specifies the URL from which to download the PEM formatted certificate bundle.

**[-ontap-version <ontap\_version>] - Certificates from specific ONTAP version**

This specifies the ONTAP version in which the certificates were introduced. Only those certificates will be loaded. This optional parameter can have an empty value (the default) which indicates that no filtering on version is done.

## Examples

The following example installs the default certificate bundle:

```
cluster1::> security certificate truststore load
```

# security config modify

Modify Security Configuration Options

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `security config modify` command modifies the existing cluster-wide security configuration. If you enable FIPS-compliant mode, the cluster will automatically select only compliant TLS protocols (currently TLSv1.3 and TLSv1.2). Non-compliant protocols are not enabled when FIPS-compliant mode is disabled. Use the `-supported-protocols` parameter to include or exclude TLS protocols independently from the FIPS mode. All protocols at or above the lowest version specified will be enabled, even those not explicitly specified. By default, FIPS mode is disabled, and Data ONTAP supports the TLSv1.3 and TLSv1.2 protocols. For backward compatibility, Data ONTAP supports adding SSLv3 and TLSv1 to the supported-protocols list when FIPS mode is disabled. Use the `-supported-cipher-suites` parameter to control which TLS cipher suites are permitted by the system.

By default the supported-cipher-suites setting is

```

TLS_RSA_WITH_AES_128_CCM,
TLS_RSA_WITH_AES_128_CCM_8,
TLS_RSA_WITH_AES_128_GCM_SHA256,
TLS_RSA_WITH_AES_128_CBC_SHA,

 TLS\_SRP\_SHA\_RSA\_WITH\_AES\_128\_CBC\_SHA, TLS\_SRP\_SHA\_RSA\_WITH\_AES\_256\_CBC\_SHA,  
 TLS\_AES\_128\_GCM\_SHA256, TLS\_AES\_256\_GCM\_SHA384, TLS\_CHACHA20\_POLY1305\_SHA256 .

Select a cipher suite which is available with the corresponding selected protocol. An invalid configuration may cause some functionality to fail to operate properly. Valid values for supported-cipher-suites are listed at "<https://www.iana.org/assignments/tls-parameters/tls-parameters.xhtml>" published by IANA.

## Parameters

### -interface <SSL> - (DEPRECATED)-FIPS-Compliant Interface

This parameter has been deprecated in ONTAP 9.8 and may be removed in a future release of Data ONTAP.

Selects the FIPS-compliant interface. The only valid value is ``\_SSL\_`` .

### [-is-fips-enabled {true|false}] - FIPS Mode

Enables or disables FIPS-compliant mode for the entire cluster. Default is **false** .

### [-supported-protocols {TLSv1.3|TLSv1.2|TLSv1.1|TLSv1|SSLv3}] - Supported Protocols

Selects the supported protocols for the selected interface. Default is **TLSv1.3,TLSv1.2**

### [-supported-ciphers <Cipher String>] - (DEPRECATED)-Supported Ciphers

This parameter has been deprecated in ONTAP 9.8 and may be removed in a future release of Data ONTAP. Use the supported-ciphers-suites parameter instead.

Selects the supported cipher suites for the selected interface. Default is ``\_ALL:!LOW:!aNULL:!EXP:!eNULL\_`` .

### [-supported-cipher-suites <Cipher String>,...] - Supported Cipher Suites

Selects the supported cipher suites for the selected interface.

## Examples

The following command enables FIPS mode in the cluster. (Default setting for FIPS mode is **false** )

```
cluster1::> security config modify * -is-fips-enabled true
```

The following command limits the supported protocols to just TLSv1.3 in the cluster. (Default setting for supported protocols is **TLSv1.3,TLSv1.2** )

```
cluster1::*> security config modify * -supported-protocols TLSv1.3
```

The following command limits the supported cipher suites in the cluster to the listed ciphers.

```
cluster1::*> security config modify * -supported-cipher-suites  
TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384,TLS_AES_256_GCM_SHA384
```

## security config show

### Display Security Configuration Options

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **security config show** command displays the security configurations of the cluster in advanced privilege mode.

Default values are as follows:

- SSL FIPS mode: disabled
- Supported protocols: TLSv1.3,TLSv1.2
- Supported cipher suites: All suites for the listed protocols except those that have no authentication, low encryption strength (less than 56 bits), or utilize 3DES or static DH key exchange.

Enabling FIPS mode will cause the entire cluster to use FIPS-compliant crypto operations only.

Use the [security config modify](#) command to change the protocols and cipher suites that the cluster will support.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**{ [-instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-interface <SSL>] - (DEPRECATED)-FIPS-Compliant Interface**

This parameter has been deprecated in ONTAP 9.8 and may be removed in a future release of Data ONTAP. As there only ever existed one valid value for this parameter, filtering on it has never altered the results.

Displays configurations that match the specified value for the interface.

**[-is-fips-enabled {true|false}] - FIPS Mode**

Display configurations that match the specified value for FIPS mode.

**[-supported-protocols {TLSv1.3|TLSv1.2|TLSv1.1|TLSv1|SSLv3}] - Supported Protocols**

Displays configurations that match the specified protocols.

**[-supported-ciphers <Cipher String>] - (DEPRECATED)-Supported Ciphers**

This parameter has been deprecated in ONTAP 9.8 and may be removed in a future release of Data ONTAP. Use the supported-cipher-suites parameter instead.

Displays the configurations that match the specified supported ciphers.

**[-supported-cipher-suites <Cipher String>, ...] - Supported Cipher Suites**

Displays the configurations that match the specified supported cipher suites.

## Examples

The following example shows the default security configurations for a cluster.

```
cluster1::> security config show
Cluster      Supported
FIPS Mode    Protocols Supported Cipher Suites
-----
false        TLSv1.3,  TLS_RSA_WITH_AES_128_CCM, TLS_RSA_WITH_AES_128_CCM_8,
             TLSv1.2,  TLS_RSA_WITH_AES_128_GCM_SHA256,
             TLS_RSA_WITH_AES_128_CBC_SHA,
             TLS_RSA_WITH_AES_128_CBC_SHA256, TLS_RSA_WITH_AES_256_CCM,
             TLS_RSA_WITH_AES_256_CCM_8,
             TLS_RSA_WITH_AES_256_GCM_SHA384,
```

- [security config modify](#)

# security config oosp disable

Disable OCSP for one or more selected applications

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **security config oosp disable** command disables the OCSP-based certificate status check for applications supporting SSL/TLS communications. For more information about the OCSP-based certificate status check for applications supporting SSL/TLS communications, see the [security config oosp show](#) command.

## Parameters

**-application <SSL/TLS Application supporting OCSP>,...** - Application Name

Use this parameter to specify the application to disable the OCSP support. To disable all applications, the value 'all' can be used. Note: You cannot specify the value 'all' with other applications.

## Examples

The following example disables the OCSP support for AutoSupport and EMS applications:

```
cluster1::*> security config oosp disable -application autosupport,ems

cluster1::> security config oosp show
Application          OCSP Enabled?
-----
autosupport         false
audit_log           true
fabricpool          true
ems                 false
kmip                true
ldap               true
6 entries were displayed.
```

The following example disables the OCSP support for all applications:

```
cluster1::*> security config oosp disable -application all
Warning: OCSP will be disabled for all applications. Any previous modifications
```

```
will be ignored.  
Do you want to continue? {y|n}: y
```

```
cluster1::*> security config ocsp show  
Application          OCSP Enabled?  
-----  
autosupport          false  
audit_log             false  
fabricpool            false  
ems                   false  
kmip                  false  
ldap                  false  
6 entries were displayed.
```

- [security config ocsp show](#)

# security config ocsp enable

Enable OCSP for one or more selected applications

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **security config ocsp enable** command enables the OCSP-based certificate status check for applications supporting SSL/TLS communications. For more information about the OCSP-based certificate status check for applications supporting SSL/TLS communications, see the [security config ocsp show](#) command.

## Parameters

**-application <SSL/TLS Application supporting OCSP>,...** - List of Applications

Use this parameter to specify the application to enable the OCSP support. To enable all applications, the value 'all' can be used. Note: You cannot specify the value 'all' with other applications.

## Examples

The following example enables the OCSP support for AutoSupport and EMS applications:

```
cluster1::*> security config ocsp enable -application autosupport,ems  
  
cluster1::> security config ocsp show
```

```
Application          OCSP Enabled?
-----
autosupport          true
audit_log            false
fabricpool           false
ems                  true
kmip                  false
ldap                 false
6 entries were displayed.
```

The following example enables the OCSP support for all applications:

```
cluster1::*> security config oosp enable -application all
Warning: OCSP will be enabled for all applications. Any previous modifications
        will be ignored.
        Do you want to continue? {y|n}: y

cluster1::*> security config oosp show
Application          OCSP Enabled?
-----
autosupport          true
audit_log            true
fabricpool           true
ems                  true
kmip                  true
ldap                 true
6 entries were displayed.
```

## Related Links

- [security config oosp show](#)

# security config oosp show

Show Online Certificate Status Protocol (OCSP) settings

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **security config oosp show** command displays the support status of the OCSP-based certificate status check for applications supporting SSL/TLS communications. If the OCSP support is enabled for an application, this check is done in addition to the certificate chain validation as part of the SSL handshake process. The OCSP-based certificate status check is done for all the certificates in the chain, provided that each certificate has the OCSP URI access points mentioned in them. If no access points are specified, the OCSP-based certificate revocation status check is ignored for that

certificate and checking continues for the rest of the certificates in the chain.

## Parameters

**{ [-fields <fieldname>, ... ]}**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ [-instance ] ]}**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-application <SSL/TLS Application supporting OCSP>] - Application Name**

Selects the application that matches this parameter value. Applications include:

- autosupport - AutoSupport
- audit\_log - Audit Logging
- fabricpool - External capacity tiers
- ems - Event Management System
- kmip - Key Management Interoperability Protocol
- ldap\_ad - Lightweight Directory Access Protocol - Active Directory (query and modify items in Active Directory)
- ldap\_nis\_namemap - Lightweight Directory Access Protocol - NIS and Name Mapping (query Unix user, group, netgroup and name mapping information)

**[-is-ocsp-enabled {true|false}] - Is OCSP-based Certificate Status Check Enabled?**

Selects the application that matches this parameter value.

## Examples

The following example displays the OCSP support for the applications supporting SSL/TLS communications:

```
cluster1::> security config oosp show
Application          OCSP Enabled?
-----
autosupport         true
audit_log           false
fabricpool          false
ems                 true
kmip                false
ldap                false
6 entries were displayed.
```

The following example displays the OCSP support for AutoSupport:

```
cluster1::*> security config oesp show -application autosupport
Application Name: autosupport
Is OCSF-based Certificate Status Check Enabled?: true
```

# security config status show

(DEPRECATED)-Display Security Configuration Status

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command has been deprecated as of 9.9 and may be removed in a future release of Data ONTAP. Reboot is no longer required to apply the security configuration, so it now always displays false.

The `'security config status show'` command displays the required reboot status of the nodes in the cluster after security configuration settings have been modified using the `<<security-config-modify,security config modify>>` command. Use this command to monitor the status of the required reboot process. When all nodes have rebooted, the cluster is ready to use the new security configuration settings.

## Parameters

`{[-fields <fieldname>,...]}`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

`{[-instance ]}`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-node {<nodename>|local}] - Node Name`

Select the node whose reboot-status you want to display.

`[-reboot-needed {true|false}] - Reboot Needed`

reboot-needed status of the node that tells if the node requires a reboot for security configuration to take effect.

## Examples

The following example displays the status of a configuration change in a four-node cluster.

```
cluster1::> security config status show
Nodes in Cluster      Reboot Needed
-----
node1                  true
node2                  true
node3                  false
node4                  false
4 entries were displayed.
```

The following example shows the output of the command after the cluster reboot process is complete.

```
cluster1::> security config status show
Nodes in Cluster      Reboot Needed
-----
node1                  false
node2                  false
node3                  false
node4                  false
4 entries were displayed.
```

## Related Links

- [security config modify](#)

# security cryptomod-fips show

Display the status of cryptomod-fips

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command displays information about the status of the cryptomod FIPS module. By default, this command displays the following information:

- Node name
- FIPS version
- Module version
- FIPS state
- Boolean indicating if module is a user-space module
- Boolean indicating if module is operating in FIPS mode
- Boolean indicating if module is currently under validation

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[ [-instance ] ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node**

Selects the nodes that match this parameter value.

**[-fips-state-text <text>] - FIPS State**

Shows the FIPS state of the module.

- POWER ON STATE
- SELF-TEST STATE
- ERROR STATE
- OPERATE STATE
- POWER OFF STATE

**[-fips-version <text>] - FIPS Version**

Shows the FIPS version.

**[-module-version <text>] - Module Version**

Shows the cryptomod FIPS module version.

**[-is-user-space-module {true|false}] - Is User Space Module?**

True if the module is a user-space module.

**[-is-fips-enabled {true|false}] - Is FIPS Mode Enabled?**

True if the module is operating in FIPS mode.

**[-is-iut-enabled {true|false}] - Is an IUT Module Enabled?**

True if the module is currently under validation.

## Examples

```
cluster1::> security cryptomod-fips show
Node   FIPS      FIPS      Module
      State    Version   Version
-----
node-1 OPERATE STATE  140-2    2.2
node-2 OPERATE STATE  140-2    2.2
```

# security ipsec show-ikesa

## Show IKE SA Information

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **security ipsec show-ikesa** command displays information about IKE Security Associations (SA).

Running this command with the **-node** parameter displays information relevant to IKE SAs generated at the specified node.

Running this command with the **-vserver** parameter displays information relevant to IKE SAs associated with the specified vservers.

Running this command with the **-policy-name** parameter displays information relevant to IKE SAs created based on the specified security policy.

You can specify additional parameters to display only information matching those parameters. For example, to display IKE SAs associated with a specific local address, run the command with the **-local-address** parameter.

## Parameters

**{ [-fields <fieldname>,...]**

If you specify the **-fields <fieldname>,...** parameter, the command displays only the specified fields. Notice that key fields are always displayed.

**[-instance ]}**

If you specify the **-instance** parameter, the command displays all fields of the IKE SAs.

**-node <nodename> - Node**

This required parameter specifies the node from which the IKE SA information will be collected and displayed.

**[-vserver <vserver name>] - Vserver Name**

Use this parameter to display the IKE SAs associated with the specified Vserver.

**[-policy-name <text>] - Policy Name**

Use this parameter to display the IKE SAs created based on the specified security policy.

**[-local-address <text>] - Local Address**

Use this parameter to display the IKE SAs with the specified local endpoint IP address.

**[-remote-address <text>] - Remote Address**

Use this parameter to display the IKE SAs with the specified remote endpoint IP address.

**[-initiator-spi <text>] - Initiator SPI**

Use this parameter to display the IKE SAs with the specified initiator Security Parameter Index (SPI).

**[-responder-spi <text>] - Responder SPI**

Use this parameter to display the IKE SAs with the specified responder SPI.

**[-is-initiator {true|false}] - Is Initiator**

Use this parameter to display the IKE SAs created when the given node matches the specified initiator role: true means initiator role and false means responder role in IKE negotiation.

**[-ike-version <integer>] - IKE Version**

Use this parameter to display the IKE SAs created using the specified IKE version.

**[-auth-method <IKE Authentication Method>] - Authentication Method**

Use this parameter to display the IKE SAs created using the specified authentication method.

**[-state <IKE SA State>] - IKE SA State**

Use this parameter to display only the IKE SAs that are in the specified state.

**[-cipher-suite <Cipher Suite Type>] - Cipher Suite**

Use this parameter to display the IKE SAs created using the specified cipher suite.

**[-lifetime <integer>] - Lifetime**

Use this parameter to display the IKE SAs with the specified remaining lifetime. Notice that lifetime keeps changing for the duration of the security association.

## Examples

This example displays all IKE SAs for node **cluster1-node1** :

```
cluster-1::> security ipsec show-ikesa -node cluster1-node1
      Policy Local          Remote
Vserver Name  Address      Address      Initiator-SPI  State
-----
vs1      Policy1
          192.186.10.1  192.186.10.2  e658e5bc7ece199e ESTABLISHED
vs2      Policy2
          192.168.20.1   192.168.20.2  8eac392028ab4f12 ESTABLISHED

  Policy Name: Policy1
  Local Address: 192.168.10.1
  Remote Address: 192.168.10.2
  Initiator SPI: e658e5bc7ece199e
  Responder SPI: 9b61befff71e8ca2
  Is Initiator: false
  IKE Version: 2
  Authentication Method: PSK
  IKE SA State: ESTABLISHED
  Cipher Suite: SUITEB_GCM256
  Lifetime: 6000
```

## security ipsec show-ipsecsa

Show IPsec SA Information

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege

level.

## Description

The **security ipsec show-ipsecsa** command displays information about IPsec Security Associations (SA).

Running the command with the **-node** parameter displays information relevant to IPsec SAs at the specified node.

Running this command with the **-vserver** parameter displays information relevant to IPsec SAs associated with the specified vservers.

Running this command with the **-policy-name** parameter displays information relevant to IPsec SAs created using the specified security policy.

You can specify additional parameters to display only information matching those parameters. For example, to display IPsec SAs only about a certain local address, run the command with the **-local-address** parameter.

## Parameters

**{ [-fields <fieldname>,...]**

If you specify the **-fields <fieldname>,...** parameter, the command displays only the specified fields. Notice that key fields are always displayed.

**[-instance ]}**

If you specify the **-instance** parameter, the command displays all fields of matching IPsec SAs.

**-node <nodename> - Node**

This required parameter specifies from which node the IPsec SA information will be collected and displayed.

**[-vserver <vserver name>] - Vserver Name**

Use this parameter to display the IPsec SAs associated with the specified Vserver.

**[-policy-name <text>] - Policy Name**

Use this parameter to display the IPsec SAs created based on the specified security policy.

**[-local-address <text>] - Local Address**

Use this parameter to display the IPsec SAs with the specified local endpoint IP address.

**[-remote-address <text>] - Remote Address**

Use this parameter to display the IPsec SAs with the specified remote endpoint IP address.

**[-inbound-spi <text>] - Inbound SPI**

Use this parameter to display the IPsec SA having the specified inbound Security Parameter Index (SPI).

**[-outbound-spi <text>] - Outbound SPI**

Use this parameter to display the IPsec SA having the specified outbound SPI.

**[-action <IPsec Action Type>] - IPsec Action**

Use this parameter to display IPsec SAs with the specified security action type, such as ESP\_TRA for ESP transport mode protection or BYPASS to bypass IPsec, or DISCARD.

**[-state <text>] - IPsec SA State**

Use the parameter to display only the IPsec SAs that are in the specified state.

**[-cipher-suite <Cipher Suite Type>] - Cipher Suite**

Use this parameter to display the IPsec SAs that use the specified cipher-suite.

**[-ib-bytes <integer>] - Inbound Bytes Processed**

Use this parameter to display the IPsec SAs matching the processed inbound bytes. Notice that ib-bytes keeps changing as inbound packets are processed.

**[-ib-pkts <integer>] - Inbound Pkts Processed**

Use this parameter to display the IPsec SAs matching the processed inbound packets. Notice that ib-pkts keeps changing as inbound packets are processed.

**[-ob-bytes <integer>] - Outbound Bytes Processed**

Use this parameter to display the IPsec SAs matching the processed outbound bytes. Notice that ob-bytes keeps changing as outbound packets are processed.

**[-ob-pkts <integer>] - Outbound Pkts Processed**

Use this parameter to display the IPsec SAs matching the processed outbound packets. Notice that ob-pkts keeps changing as outbound packets are processed.

**[-lifetime <integer>] - IPsec SA Lifetime Seconds**

Use this parameter to display the IPsec SAs matching the remaining lifetime. Notice that lifetime keeps changing for the duration of the security association.

## Examples

The this example displays all IPsec SAs for node **cluster1-node1** :

```
cluster-1::> security ipsec show-ipsecsa -node cluster1-node1
      Policy  Local      Remote      Inbound  Outbound
Vserver  Name    Address      Address      SPI      SPI      State
-----
vs1      Policy1
          192.186.10.1  192.186.10.2  c68de9db  c84f913b  INSTALLED
vs2      Policy2
          192.186.20.1  192.186.20.2  cbc01493  c6ee7424  INSTALLED
2 entries were displayed.
```

This example displays selected fields of all IPsec SAs for node **cluster1-node1** :

```
cluster-1::> security ipsec show-ipsecsa -node cluster1-node1 -fields local-
address,remote-address,inbound-spi,outbound-spi
node          vserver policy-name local-address  remote-address inbound-spi outbound-
spi
-----
-----
cluster1-node1 vs1      Policy1      192.186.10.1  192.186.10.2  c68de9db      c84f913b
cluster1-node1 vs2      Policy2      192.186.20.1  192.186.20.2  cbc01493      c6ee7424
2 entries were displayed.
```

This example displays selected fields of all IPsec SAs associated with node ```_cluster1-node1_```:

```
cluster-1::> security ipsec show-ipsecsa -node cluster1-node1 -fields ib-bytes,ib-
pkts,ob-bytes,ob-pkts
node          vserver policy-name local-address  remote-address inbound-spi ib-bytes
ib-pkts ob-bytes ob-pkts
-----
-----
cluster1-node1 vs1      Policy1      192.186.10.1  192.186.10.2  c68de9db      4704
56      6720      56
cluster1-node1 vs2      Policy2      192.186.20.1  192.186.20.2  cbc01493      20434
115     23082     120
2 entries were displayed.
```

This example displays instance view (all fields) for all IPsec SAs associated with node **cluster1-node1** , vserver **vs1** and created using policy **Policy1** :

```
cluster-1::> security ipsec show-ipsecsa -node cluster1-node1 -vserver vs1 -policy
-name Policy1 -instance
Node: cluster1-node1
    Vserver Name: vs1
    Policy Name: Policy1
    Inbound SPI: c68de9db
    Outbound SPI: c84f913b
    Local Address: 192.168.10.1
    Remote Address: 192.168.10.2
    IPsec Action: ESP_TRA
    IPsec SA State: INSTALLED
    Cipher Suite: SUITEB_GCM256
    Inbound Bytes Processed: 4704
    Inbound Pkts Processed: 56
    Outbound Bytes Processed: 6720
    Outbound Pkts Processed: 56
    IPsec SA Lifetime Seconds: 1800
```

# security ipsec ca-certificate add

Add CA certificate(s) to a vserver

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command adds a list of CA certificates to IPsec for the given Vserver. These certificates will be used for PKI authentication with remote IKE endpoint. The CA certificates should have already been installed using either [security certificate install](#) command or [security certificate create](#) command.

## Parameters

**-vserver <vserver name> - Vserver Name**

Use this parameter to specify the Vserver for which the IPsec CA certificates should be added.

**-ca-certs <text>,... - CA Certificate Names**

Use this parameter to specify the list of CA certificates to be added to IPsec.

## Examples

The following example adds two IPsec CA certificates named caCert1 and caCert2 to Vserver v1.

```
cluster-1::>security ipsec ca-certificate add -vserver v1 -ca-certs caCert1,caCert2
```

## Related Links

- [security certificate install](#)
- [security certificate create](#)

# security ipsec ca-certificate remove

Remove CA certificate(s) from a vserver

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command removes a list of IPsec CA certificates for the given Vserver. The CA certificates being removed should have been previously added to IPsec using [security ipsec ca-certificate add](#)

command.

## Parameters

### **-vserver <vserver name> - Vserver Name**

Use this parameter to specify the Vserver for which the IPsec CA certificates should be removed.

### **-ca-certs <text>,... - CA Certificate Names**

Use this parameter to specify the list of CA certificates to be removed from IPsec.

## Examples

The following example removes two IPsec CA certificates named caCert1 and caCert2 for Vserver v1.

```
cluster-1::>security ipsec ca-certificate remove -vserver v1 -ca-certs caCert1,caCert2
```

## Related Links

- [security ipsec ca-certificate add](#)

# security ipsec ca-certificate show

Displays the CA certificates added to IPsec

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command displays the configured IPsec CA certificates.

## Parameters

{ [-fields <fieldname>,...]

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

| [-instance ] }

If you specify the **-instance** parameter, the command displays detailed information about all fields.

[-vserver <vserver name>] - Vserver Name

If you specify this parameter, then the command displays only the IPsec CA certificates configured for the given vserver.

**[-ca-certs <text>,...] - CA Certificate Names**

If you specify this parameter, then the command displays only the Vservers for which the given CA certificates are present in IPsec.

## Examples

The following example lists the IPsec CA certificates configured for all Vservers.

```
cluster-1::>security ipsec ca-certificate show
```

Vserver	CA Certificate Names
v1	caCert1, caCert2
v2	caCert3, caCert4

2 entries were displayed.

# security ipsec config modify

## Modify IPsec config

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command modifies IPsec configuration parameters.

## Parameters

**[-is-enabled {true|false}] - Is IPsec Enabled**

This parameter enables and disables IPsec on the storage system.

**[-log-level <IPsec Log Level>] - IPsec Logging Level**

This parameter sets the IPsec logging level, where logging level 0 means no logging, and logging level 5 is most verbose. Default value is 2.

**[-replay-window {0|64|128|256|512|1024}] - IPsec Replay Window Size**

This parameter sets the IPsec replay window size. The possible values are 0, 64, 128, 256, 512 and 1024. Default value is 0.

**[-ready-to-downgrade {true|false}] - IPsec Ready To Downgrade**

This parameter is used when downgrade to a non-IPsec capable ONTAP. Set this parameter to true to cleanup IPsec configurations before such downgrade.

## Examples

The following example enables IPsec:

```
cluster-1::> security ipsec config modify -is-enabled true
```

The following example sets the IPsec logging level to 4:

```
cluster-1::> security ipsec config modify -log-level 4
```

The following example sets the IPsec replay window size to 64:

```
cluster-1::> security ipsec config modify -replay-window 64
```

## security ipsec config show

Display IPsec config

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command shows the current IPsec configuration parameters.

## Examples

The following example shows the state of IPsec (enabled/disabled) and the IPsec logging level:

```
cluster-1::> security ipsec config show
  IPsec Enabled: false
  IPsec Log Level: 2
  Replay Window Size: 0
```

## security ipsec policy create

Create an IPsec policy

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command creates a new IPsec policy. The traffic to be protected is specified by the traffic selectors (local-ip-subnets, remote-ip-subnets, local-ports, remote-ports, protocols). IPsec is not supported for the admin Vserver in a MetroCluster environment.

## Parameters

### **-vserver <vserver name> - Vserver**

Specifies the Vserver to which the policy will belong. If there is only a single Vserver capable of supporting IPsec, the Vserver parameter is implied.

### **-name <text> - Policy Name**

This required parameter specifies the name of the policy which may be a text string (1-64 bytes), a hexadecimal string (beginning with '0x') or a base64 encoded binary string (beginning with '0s').

### **-local-ip-subnets <IP Address/Mask>, ... - Local IP Subnets**

This required parameter specifies the IPv4 or IPv6 subnet (address and mask, can be subnet or individual address) representing the local address (range) to be protected by this policy.

### **-remote-ip-subnets <IP Address/Mask>, ... - Remote IP Subnets**

This required parameter specifies the IPv4 or IPv6 subnet (address and mask, can be subnet or individual address) representing the remote address (range) to be protected by this policy.

### **[-local-ports {<Number>|<StartingNumber>-<EndingNumber>}] - Local Ports**

This optional parameter specifies logical port associated with the local address to be protected by this policy. The port defaults to any port ('0-0' or '0') but a single port may be specified ('port number' or 'port number-port number').

### **[-remote-ports {<Number>|<StartingNumber>-<EndingNumber>}] - Remote Ports**

This optional parameter specifies logical port associated with the remote address to be protected by this policy. The port defaults to any port ('0-0' or '0') but a single port may be specified ('port number' or 'port number-port number').

### **[-protocols {<Protocol Number>|<Protocol Name>}] - Protocols**

This optional parameter specifies the protocol to be protected by by this policy. The protocol defaults to any protocol ('any' or '0') but a single protocol may be specified ('tcp', 'udp' or protocol number).

### **[-action <IPsec Action Type>] - Action**

This optional parameter specifies the action to be performed when a packet meets the traffic selectors described by this policy. The possible values are 'ESP\_TRA' (IPsec protect traffic), 'DISCARD' (discard matching traffic), or 'BYPASS' (send matching traffic in cleartext (not protected by IPsec)). NOTE: if the action is 'ESP\_TRA', then 'shared-key' becomes a required parameter. If the action is 'BYPASS' or 'DISCARD' and a shared-key is provided, then the shared-key value will be ignored and discarded. The default value is 'ESP\_TRA'.

**[-cipher-suite <Cipher Suite Type>] - Cipher Suite**

This optional parameter specifies the suite of algorithms that will be used to protect the traffic. The possible values are:

SUITEB\_GCM256: Suite-B-GCM-256 cipher suite as specified in RFC6379.

SUITEB\_GMAC256: Suite-B-GMAC-256 cipher suite as specified in RFC6379.

SUITE\_AESCBC: Suite consisting of AES256 CBC and SHA512 for ESP and AES256-SHA512-MODP4096 for IKE.

The default value is 'SUITEB\_GCM256'.

**[-ike-lifetime <integer>] - IKE Security Association Lifetime**

This optional parameter specifies the lifetime of an IKE Security Association (in seconds). Shortly before the expiration of the IKE-lifetime, a new IKE security association will be created and the existing IKE security association (and child IPsec security associations) will be destroyed. The default value is 86400 seconds.

**[-ipsec-lifetime <integer>] - IPsec Security Association Lifetime**

This optional parameter specifies the lifetime of an IPsec Security Association (in seconds). Shortly before the expiration of the ipsec-lifetime, a new IPsec security association will be created and the existing IPsec security association will be destroyed. The default value is 28800 seconds.

**[-ipsec-lifetime-bytes <integer>] - IPsec Security Association Lifetime (bytes)**

This optional parameter specifies the byte lifetime of an IPsec Security Association. Shortly before the expiration of the ipsec-lifetime-bytes (ipsec-lifetime-bytes have been processed by the IPsec security association), a new IPsec security association will be created and the existing IPsec security association will be destroyed. The default value is 0, i.e infinity bytes.

**[-is-enabled {true|false}] - Is Policy Enabled**

This optional parameter specifies whether the IPsec policy is enabled or not. Any policy that is created is stored in a replicated database. The 'is-enabled' parameter determines if the policy will be included in those evaluated when determining the best-matched policy to match the traffic selectors of the packet. The default value is 'true'.

**[-local-identity <text>] - Local Identity**

This optional parameter specifies the local IKE endpoint's identity for authentication purpose. If this field is not explicitly specified, local-ip-subnet will assume the role for identity. If this field is set to "ANYTHING", then it will be translated to the strongSwan "%any" special identity.

**[-remote-identity <text>] - Remote Identity**

This optional parameter specifies the remote IKE endpoint's identity for authentication purpose. If this field is not explicitly specified, remote-ip-subnet will assume the role for identity. If this field is set to "ANYTHING", then it will be translated to the strongSwan "%any" special identity.

**[-auth-method <IKE Authentication Method>] - Authentication Method**

This optional parameter specifies the authentication method for an IPsec policy. The default value

is 'PSK', the pre-shared key authentication method.

### **[-cert-name <text>] - Certificate for Local Identity**

This parameter specifies the certificate name and is mandatory for an IPsec policy using the PKI authentication method. The certificate should have already been installed using [security certificate install](#) command.

## Examples

This is an example of the creation of an IPsec policy that protects matching traffic, with all parameters specified. The preshared key can be string of length 18-128 bytes, a sequence hexadecimal digits beginning with 0x or a sequence of Base64 encoded binary data with 0s.

```
cluster-1::> security ipsec policy create -vserver vs_data1 -name Policy1 -local-ip
-subnets 192.168.10.1/32 -remote-ip-subnets 192.168.20.1/32 -local-ports 4000 -remote
-ports 5001 -protocols tcp -action ESP_TRA -shared-key
This_is_a_shared_key_for_ipsec_policy -ike-version 2 -cipher-suite SUITEB_GCM256 -ike
-lifetime 4000 -ipsec-lifetime 1800 -ipsec-lifetime-bytes 104880 -is-enabled true
```

Enter the preshared key for IPsec Policy "Policy1" on Vserver "vs\_data1":  
Re-enter the preshared key:

This is an example of the creation of an IPsec policy that protects matching traffic, with some parameters specified (others will be using the default values). PKI authentication method . is used. In this example, remote-identity does not matter, as long as a trusted certificate is provided.

```
cluster-1::> security ipsec policy create -vserver vs_data1 -name Policy2 -local-ip
-subnets 192.168.10.1/32 -remote-ip-subnets 0.0.0.0/0 -local-ports 2049 -auth-method
PKI -cert-name lifcert -local-identity "CN=lif1_certificate.netapp.com" -remote
-identity ANYTHING
```

This is an example of the creation of an IPsec policy that discards matching traffic:

```
cluster-1::> security ipsec policy create -vserver vs_data1 -name DiscardTraffic
-local-ip-subnets 192.168.10.1/32 -remote-ip-subnets 192.168.20.1/32 -action DISCARD
```

## Related Links

- [security certificate install](#)

# security ipsec policy delete

Delete an IPsec policy

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command deletes an existing IPsec policy.

## Parameters

### **-vserver <vserver name> - Vserver**

Specifies the Vserver to which the policy belongs. If there is only a single Vserver capable of supporting IPsec, the Vserver parameter is implied.

### **-name <text> - Policy Name**

This required parameter specifies the name of the policy to be deleted. The name may be a text string (1-64 bytes), a hexadecimal string (beginning with '0x') or a base64 encoded binary string (beginning with '0s').

## Examples

This is an example of IPsec policy deletion where two or more Vservers are capable of supporting IPsec:

```
cluster-1::> security ipsec policy delete -vserver vs_data1 -name DiscardTraffic
```

This is an example of IPsec policy deletion where only a single Vserver is capable of supporting IPsec:

```
cluster-1::> security ipsec policy delete -name policy1
```

This is an example of an attempt to delete a non-existent IPsec policy:

```
cluster-1::> security ipsec policy delete -vserver vs_data1 -name Discard
```

```
Error: There are no entries matching your query.
```

## security ipsec policy modify

Modify an IPsec policy

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command modifies an existing IPsec policy. You cannot modify the name or vserver of a policy. Moving a policy from one Vserver to another or renaming a policy requires that the existing policy be deleted and then a new policy created in the desired Vserver with the desired name.

It is highly recommended that the user set the field **-is-enabled** to **false** prior to making any other modifications to the policy. This will disable the policy and allow all existing IPsec and IKE Security Associations associated with policy to get flushed. Then, the user can modify the policy with the desired changes, along with setting the **-is-enabled** field to **true** to re-enable the policy.

## Parameters

### **-vserver <vserver name> - Vserver**

Specifies the Vserver to which the policy belongs. If there is only a single Vserver capable of supporting IPsec, the Vserver parameter is implied.

### **-name <text> - Policy Name**

This required parameter specifies the name of the policy which may be a text string (1-64 bytes), a hexadecimal string (beginning with '0x') or a base64 encoded binary string (beginning with '0s').

### **[-local-ip-subnets <IP Address/Mask>, ...] - Local IP Subnets**

This parameter specifies the IPv4 or IPv6 subnet (address and mask, can be subnet or individual address) representing the local address (range) to be protected by this policy.

### **[-remote-ip-subnets <IP Address/Mask>, ...] - Remote IP Subnets**

This parameter specifies the IPv4 or IPv6 subnet (address and mask, can be subnet or individual address) representing the remote address (range) to be protected by this policy.

### **[-local-ports {<Number>|<StartingNumber>-<EndingNumber>}] - Local Ports**

This parameter specifies the logical port associated with the local address to be protected by this policy. The value may be specified by 'port number' or 'port number-port number'.

### **[-remote-ports {<Number>|<StartingNumber>-<EndingNumber>}] - Remote Ports**

This parameter specifies the logical port associated with the remote address to be protected by this policy. The value may be specified by 'port number' or 'port number-port number'.

### **[-protocols {<Protocol Number>|<Protocol Name>}] - Protocols**

This parameter specifies the protocol to be protected by this policy. The protocol may be specified as 'tcp', 'udp' or protocol number.

### **[-cipher-suite <Cipher Suite Type>] - Cipher Suite**

This parameter specifies the suite of algorithms that will be used to protect the traffic. The possible values are:

SUITEB\_GCM256: Suite-B-GCM-256 cipher suite as specified in RFC6379.

SUITEB\_GMAC256: Suite-B-GMAC-256 cipher suite as specified in RFC6379.

SUITE\_AESCBC: Suite consisting of AES256 CBC and SHA512 for ESP and AES256-SHA512-MODP4096 for IKE.

The default value is 'SUITEB\_GCM256'.

#### **[-ike-lifetime <integer>] - IKE Security Association Lifetime**

This parameter specifies the lifetime of an IKE Security Association (in seconds). Shortly before the expiration of the IKE-lifetime, a new IKE security association will be created and the existing IKE security association (and child IPsec security associations) will be destroyed.

#### **[-ipsec-lifetime <integer>] - IPsec Security Association Lifetime**

This parameter specifies the lifetime of an IPsec Security Association (in seconds). Shortly before the expiration of the ipsec-lifetime, a new IPsec security association will be created and the existing IPsec security association will be destroyed.

#### **[-ipsec-lifetime-bytes <integer>] - IPsec Security Association Lifetime (bytes)**

This parameter specifies the byte lifetime of an IPsec Security Association. Shortly before the expiration of the ipsec-lifetime-bytes (ipsec-lifetime-bytes have been processed by the IPsec security association), a new IPsec security association will be created and the existing IPsec security association will be destroyed.

#### **[-is-enabled {true|false}] - Is Policy Enabled**

This parameter specifies the whether the IPsec policy is enabled or not. Any policy which is created is stored in a replicated database. The 'is-enabled' parameter determines if the policy will be included in those evaluated when determining the best-matched policy to match the traffic selectors of the packet. The default value is 'true'.

#### **[-local-identity <text>] - Local Identity**

This optional parameter specifies the local IKE endpoint's identity for authentication purpose. If this field is not explicitly specified, local-ip-subnet will assume the role for identity. If this field is set to "ANYTHING", then it will be translated to the strongSwan "%any" special identity.

#### **[-remote-identity <text>] - Remote Identity**

This optional parameter specifies the remote IKE endpoint's identity for authentication purpose. If this field is not explicitly specified, remote-ip-subnet will assume the role for identity. If this field is set to "ANYTHING", then it will be translated to the strongSwan "%any" special identity.

#### **[-cert-name <text>] - Certificate for Local Identity**

This optional parameter specifies the certificate name for an IPsec policy using PKI authentication method.

## Examples

The following example modifies the local-ip-subnets value of an IPsec policy:

```
cluster-1::> security ipsec policy modify -vserver vs_data1 -name Policy1 -local-ip  
-subnets 192.168.30.2/32
```

# security ipsec policy show

Display IPsec policies

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **security ipsec policy show** command displays information about configured IPsec policies. All parameters are optional. This command is supported only when IPsec is enabled.

Running the command with the **-vserver** parameter displays all policies associated with the specified vserver.

You can specify additional parameters to display only information that matches those parameters. For example, to display policies associated with a certain local ip subnet, run the command with the **-local-ip-subnets** parameter.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command displays only the specified fields. Notice that key fields are always displayed.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays all fields of the policies.

**[ -vserver <vserver name> ] - Vserver**

If you specify this parameter, only policies associated with this Vserver will be displayed.

**[ -name <text> ] - Policy Name**

This parameter specifies the policy to be displayed.

**[ -local-ip-subnets <IP Address/Mask>, ... ] - Local IP Subnets**

If you specify this parameter, information about local-ip-subnets will be displayed.

**[ -remote-ip-subnets <IP Address/Mask>, ... ] - Remote IP Subnets**

If you specify this parameter, information about remote-ip-subnets will be displayed.

**[ -local-ports {<Number>|<StartingNumber>-<EndingNumber>} ] - Local Ports**

If you specify this parameter, information about local-ports will be displayed.

**[-remote-ports {<Number>|<StartingNumber>-<EndingNumber>}] - Remote Ports**

If you specify this parameter, information about remote-ports will be displayed.

**[-protocols {<Protocol Number>|<Protocol Name>}] - Protocols**

If you specify this parameter, information about protocols will be displayed.

**[-action <IPsec Action Type>] - Action**

If you specify this parameter, information about action will be displayed.

**[-cipher-suite <Cipher Suite Type>] - Cipher Suite**

If you specify this parameter, information about cipher-suite will be displayed.

**[-ike-lifetime <integer>] - IKE Security Association Lifetime**

If you specify this parameter, information about ike-lifetime will be displayed.

**[-ipsec-lifetime <integer>] - IPsec Security Association Lifetime**

If you specify this parameter, information about ipsec-lifetime will be displayed.

**[-ipsec-lifetime-bytes <integer>] - IPsec Security Association Lifetime (bytes)**

If you specify this parameter, information about ipsec-lifetime-bytes will be displayed.

**[-is-enabled {true|false}] - Is Policy Enabled**

If you specify this parameter, information about is-enabled will be displayed.

**[-local-identity <text>] - Local Identity**

If you specify this parameter, information about local IKE endpoint's identity, if configured, will be displayed.

**[-remote-identity <text>] - Remote Identity**

If you specify this parameter, information about remote IKE endpoint's identity, if configured, will be displayed.

**[-auth-method <IKE Authentication Method>] - Authentication Method**

If you specify this parameter, the authentication method of the policy will be displayed.

**[-cert-name <text>] - Certificate for Local Identity**

If you specify this parameter, the name of the certificate will be displayed.

## Examples

The this example displays all policies in all Vservers:

```
cluster-1::> security ipsec policy show
      Policy
Vserver Name      Local IP Subnet      Remote IP Subnet      Cipher
                   Suite              Action
-----
vs_data1
```

```
security ipsec policy show
```

```

Policy1 192.168.10.1/32 192.168.20.1/32 SUITEB_GCM256 ESP_TRA
Policy3 192.158.10.10/32 192.158.10.20/32 SUITEB_GCM256 DISCARD
vs_data2
Policy2 10.10.10.10/32 20.20.20.20/32 SUITE_AESCBC ESP_TRA
3 entries were displayed.
```

This example displays all of the IPsec policies from a single Vserver:

```

cluster-1::> security ipsec policy show -vserver vs_data1
Policy
Vserver Name      Local IP Subnet      Remote IP Subnet      Cipher Suite          Action
-----
vs_data1
Policy1 192.168.10.1/32 192.168.20.1/32 SUITEB_GCM256 ESP_TRA
Policy3 192.158.10.10/32 192.158.10.20/32 SUITEB_GCM256 DISCARD
2 entries were displayed.
```

This example displays a specific policy:

```

cluster-1::> security ipsec policy show -vserver vs_data1 -name Policy1
Vserver Name: vs_data1
Policy Name: Policy1
Local IP Subnets: 192.168.10.1/32
Remote IP Subnets: 192.168.20.1/32
Local Ports: 0-0
Remote Ports: 0-0
Protocols: any
Action: ESP_TRA
Cipher Suite: SUITEB_GCM256
IKE Security Association Lifetime: 10800
IPsec Security Association Lifetime: 3600
IPsec Security Association Lifetime (bytes): 0
Is Policy Enabled: true
Local Identity:
Remote Identity:
```

This example displays a specific field from all policies:

```

cluster-1::> security ipsec policy show -fields local-ip-subnets
vserver name      local-ip-subnets
-----
vs_data1 Policy1 192.168.10.1/32
vs_data1 Policy3 192.158.10.10/32
vs_data2
Policy2 10.10.10.10/32
3 entries were displayed.
```

# security key-manager add

(DEPRECATED)-Add a key management server

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command is deprecated and may be removed in a future release. Use [security key-manager external add-servers](#) instead.

This command adds a key management server at the indicated IP address to its list of four possible active key management servers. The command fails if there are already four key management servers configured. This command is not supported when the Onboard Key Manager is enabled.

## Parameters

### **-address <IP Address> - IP Address**

This parameter specifies the IP address of the key management server you want to use to store keys.

### **[-server-port <integer>] - Server TCP Port**

This parameter specifies the TCP port on which the key management server will listen for incoming connections.

## Examples

The following example adds the key management server with address 10.233.1.98, listening for incoming connections on the default TCP port 5696, to the list of key management servers used by the external key manager:

```
cluster-1::> security key-manager add -address 10.233.1.198
```

The following example adds the key management server with address 10.233.1.98, listening for incoming connections on TCP port 15696, to the list of key management servers used by the external key manager:

```
cluster-1::> security key-manager add -address 10.233.1.198 -server-port 15696
```

# security key-manager create-key

(DEPRECATED)-Create a new authentication key

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command is deprecated and may be removed in a future release. Use [security key-manager key create](#) instead.

This command creates a new authentication key (AK) and stores it on the configured key management servers. The command fails if the configured key management servers are already storing more than 128 AKs. If command fails due to more than 128 keys in cluster, delete unused keys on your key management servers and try the command again. This command is not supported when the Onboard Key Manager is enabled.

## Parameters

### **[-key-tag <text>] - Key Tag**

This parameter specifies the key tag that you want to associate with the new authentication key (AK). The default value is the node name. This parameter can be used to help identify created authentication keys (AKs). For example, the key-manager query command key-tag parameter can be used to query for a specific key-tag value.

### **[-prompt-for-key {true|false}] - Prompt for Authentication Passphrase**

If you specify this parameter as true, the command prompts you to enter an authentication passphrase manually instead of generating it automatically. For security reasons, the authentication passphrase you entered is not displayed at the command prompt. You must enter the authentication passphrase a second time for verification. To avoid errors, copy and paste authentication passphrases electronically instead of entering them manually. Data ONTAP saves the resulting authentication key/key ID pair automatically on the configured key management servers.

## Examples

The following example creates an authentication key with the node name as the default key-tag value:

```
cluster-1::> security key-manager create-key

Verifying requirements...

Node: node1
Creating authentication key...
Authentication key creation successful.
```

```
Key ID: 0000000000000000020000000000100D0F7C2462D626B739FE81B89F29A092F.
```

```
Node: node2
```

```
Key manager restore operation initialized.
```

```
Successfully restored key information.
```

The following example creates an authentication key with key-tag "disk1-key":

```
cluster-1::> security key-manager create-key -key-tag disk1-key
```

```
Verifying requirements...
```

```
Node: node1
```

```
Creating authentication key...
```

```
Authentication key creation successful.
```

```
Key ID: 0000000000000000020000000000100B8297A6189BC24B9B84C1916ED576857.
```

```
Node: node2
```

```
Key manager restore operation initialized.
```

```
Successfully restored key information.
```

The following example creates an authentication key with a user-specified authentication passphrase:

```
cluster-1::> security key-manager create-key -prompt-for-key true
```

```
Enter a new passphrase::
```

```
Reenter the passphrase::
```

```
Verifying requirements...
```

```
Node: node1
```

```
Creating authentication key...
```

```
Authentication key creation successful.
```

```
Key ID: 00000000000000000200000000001006268333F870860128FBE17D393E5083B.
```

```
Node: node2
```

```
Key manager restore operation initialized.
```

```
Successfully restored key information.
```

# security key-manager delete-key-database

(DEPRECATED)-Deletes the key hierarchy for the Onboard Key Manager

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command is deprecated and might be removed in a future release. Use [security key-manager onboard disable](#) instead.

The **security key-manager delete-key-database** command permanently deletes the Onboard Key Manager configuration from all nodes of the cluster.

## Examples

The following example deletes the Onboard Key Manager configuration from all nodes of the cluster:

```
cluster-1::*> security key-manager delete-key-database
```

```
Warning: This command will permanently delete all keys from the Onboard Key Manager.  
Do you want to continue? {y|n}: y
```

## Related Links

- [security key-manager onboard disable](#)

# security key-manager delete-kmip-config

(DEPRECATED)-Deletes the KMIP configuration

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command is deprecated and may be removed in a future release. Use [security key-manager external disable](#) instead.

The **security key-manager delete-kmip-config** command permanently deletes the Key Management Interoperability Protocol (KMIP) server configuration from all nodes of the cluster.

The keys stored by the external KMIP servers cannot be deleted by Data ONTAP, and must be deleted by using external tools.

## Examples

The following example deletes the KMIP-server configuration from all nodes of the cluster:

```
cluster-1::*> security key-manager delete-kmip-config

Warning: This command will permanently delete the KMIP-server configuration
        from all nodes of the cluster.
Do you want to continue? {y|n}: y
The KMIP-server configuration has been deleted from all nodes of the cluster.
The keys stored by the external KMIP servers cannot be deleted by Data ONTAP,
and must be deleted by using external tools.
```

## Related Links

- [security key-manager external disable](#)

# security key-manager delete

(DEPRECATED)-Delete a key management server

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command is deprecated and may be removed in a future release. Use [security key-manager external remove-servers](#) instead.

This command removes the key management server at the indicated IP address from the list of active key management servers. If the indicated key management server is the sole storage location for any key that is in use by Data ONTAP, you will be unable to remove the key server. This command is not supported when the Onboard Key Manager is enabled.

## Parameters

**-address <IP Address> - IP Address**

This parameter specifies the IP address of the key management server you want to remove from use.

## Examples

The following example removes the key server at IP address 10.233.1.198 from the set of configured key management servers:

```
cluster-1::> security key-manager delete -address 10.233.1.198
```

## Related Links

- [security key-manager external remove-servers](#)

# security key-manager prepare-to-downgrade

Prepares all configured Key managers for downgrade

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command is deprecated and might be removed in a future release.

The **security key-manager prepare-to-downgrade** command disables the Onboard Key Manager features that are not supported in releases prior to ONTAP 9.1.0. The features that are disabled are Onboard Key Manager support for Metrocluster configurations and Volume Encryption (VE).

## Examples

The following example disables the Onboard Key Manager support for Metrocluster configurations and Volume Encryption (VE):

```
cluster1::*> security key-manager prepare-to-downgrade
```

# security key-manager query

(DEPRECATED)-Display the key IDs stored in a key management server.

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command is deprecated and may be removed in a future release. Use [security key-manager key query](#) instead.

This command displays the IDs of the keys that are stored on the key management servers. This command does not update the key tables on the node. To refresh the key tables on the nodes with the key management server key tables, run the [security key-manager restore](#) command. This command is not supported when the Onboard Key Manager is enabled.

## Parameters

### {[-fields <fieldname>,...]}

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

### [-instance ]}

If you specify the **-instance** parameter, the command displays detailed information about all fields.

### [-node {<nodename>|local}] - Node

This parameter specifies the name of the node that queries the specified key management servers. If this parameter is not specified, then all nodes will query the specified key management servers.

### [-address <IP Address>] - IP Address

This parameter specifies the IP address of the key management server that you want to query.

### [-key-id <key id>] - Key ID

If you specify this parameter, then the command displays only the key IDs that match the specified value.

### [-key-tag <text>] - Key Tag

If you specify this parameter, then the command displays only the key IDs that match the specified value. The key-tag for Volume Encryption Keys (VEKs) is set to the UUID of the encrypted volume.

### [-key-type <Key Usage Type>] - Key Type

If you specify this parameter, then the command displays only the key IDs that match the specified value.

### [-count <integer>] - (DEPRECATED)-Key Server's Total Key Count

The value **count** is deprecated and may be removed in a future release of Data ONTAP. This parameter specifies the total number of keys stored in the key management servers. If you specify this parameter, then the command displays only the key IDs retrieved from the key management servers whose total key count matches the specified count number.

### [-restored {yes|no}] - Key/Key ID Pair Present in Node's Key Table?

This parameter specifies whether the key corresponding to the displayed key ID is present in the specified node's internal key table. If you specify 'yes' for this parameter, then the command displays the key IDs of only those keys that are present in the system's internal key table. If you specify 'no' for this parameter, then the command displays the key IDs of only those keys that are not present in the system's internal key table.

### [-key-manager-server-status {available|not-responding|unknown}] - Command Error Code

This parameter specifies the connectivity status of the key management server. If you specify this parameter, then the command displays only the key IDs retrieved from the key management

servers with specified status.

## Examples

The following example shows all the keys on all configured key servers, and whether those keys have been restored for all nodes in the cluster:

```
cluster-1::> security key-manager query
Node: node1
  Key Manager: 10.0.0.10
  Server Status: available

Key Tag                                Key Type  Restored
-----
node1                                    NSE-AK    yes
  Key ID:
00000000000000000200000000001001d71f3b2468d7e16a6e6972d3e664520000000000000000
301a4e57-9efb-11e7-b2bc-0050569c227f  VEK      yes
  Key ID:
00000000000000000200000000005004d03aca5b72cd20b2f83eae1531c605e000000000000000
Node: node2
  Key Manager: 10.0.0.10
  Server Status: available

Key Tag                                Key Type  Restored
-----
node1                                    NSE-AK    yes
  Key ID:
00000000000000000200000000001001d71f3b2468d7e16a6e6972d3e664520000000000000000
301a4e57-9efb-11e7-b2bc-0050569c227f  VEK      no
  Key ID:
00000000000000000200000000005004d03aca5b72cd20b2f83eae1531c605e000000000000000

If any listed keys have "no" in the "Restored" column, run "security key-manager
restore" to restore those keys.
```

The following example shows all keys stored on the key server with address "10.0.0.10" from node "node1" with key-tag "node1":

```
cluster-1::> security key-manager query -address 10.0.0.10 -node node1 -key-tag node1
Node: node1
  Key Manager: 10.0.0.10
  Server Status: available

Key Tag                                Key Type  Restored
-----
node1                                    NSE-AK    yes
  Key ID:
```

```
000000000000000002000000000001001d71f3b2468d7e16a6e6972d3e664520000000000000000
```

If any listed keys have "no" in the "Restored" column, run "security key-manager restore" to restore those keys.

The following example shows the Volume Encryption Key (VEK) with key-tag (i.e., volume UUID) "301a4e57-9efb-11e7-b2bc-0050569c227f" on nodes where that key has not been restored:

```
cluster-1::*> security key-manager query -key-type VEK -key-tag 301a4e57-9efb-11e7-
b2bc-0050569c227f -restored no
```

```
Node: node2
```

```
Key Manager: 10.0.0.10
```

```
Server Status: available
```

Key Tag	Key Type	Restored
301a4e57-9efb-11e7-b2bc-0050569c227f	VEK	no

Key ID:  
000000000000000002000000000005004d03aca5b72cd20b2f83eae1531c605e0000000000000000

If any listed keys have "no" in the "Restored" column, run "security key-manager restore" to restore those keys.

# security key-manager restore

(DEPRECATED)-Restore the key ID pairs from the key management servers.

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command is deprecated and may be removed in a future release. Use [security key-manager external restore](#) instead.

This command retrieves and restores any current unrestored keys associated with the storage controller from the specified key management servers. This command is not supported when the Onboard Key Manager is enabled.

## Parameters

### { [-fields <fieldname>, ... ] }

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

### [ [-instance ] ] }

If you specify the **-instance** parameter, the command displays detailed information about all fields.

### [ -node {<nodename>|local} ] - Node

This parameter specifies the name of the node that is to load the key IDs into its internal key table. If not specified, all nodes retrieve keys into their internal key table.

### [ -address <IP Address> ] - IP Address

If this parameter is specified, the command restores only from key management server at the specified IP address. If not specified the command restores from all available key management servers.

### [ -key-id <key id> ] - Key ID

If this parameter is specified, the command restores only the specified key IDs.

### [ -key-tag <text> ] - Key Tag

This parameter specifies the value associated with the key ID pair at the time of their creation. If specified, restore only key ID pairs associated with the specified key tag. If not specified, all key ID pairs for the cluster are retrieved.

### [ -count <integer> ] - (DEPRECATED)-Key Server's total Key Count

The value **count** is deprecated and may be removed in a future release of Data ONTAP. This parameter specifies the total number of keys stored in the key management servers. If this parameter is specified, then the command displays only the key IDs retrieved from the key management servers whose total key count matches the specified count number.

### [ -key-manager-server-status {available|not-responding|unknown} ] - Command Error Code

This parameter specifies the connectivity status of the key management server. If you specify this parameter the command displays only the key IDs retrieved from key management servers with specified status.

## Examples

The following command restores keys that are currently on a key server but are not stored within the key tables on the cluster:

```
cluster-1::> security key-manager restore
Node: node1
  Key Manager: 10.0.0.10
  Server Status: available
```

## Key IDs

```
-----
000000000000000000002000000000001001d71f3b2468d7e16a6e6972d3e664520000000000000000
000000000000000000002000000000005004d03aca5b72cd20b2f83eae1531c605e000000000000000
Node: node2
  Key Manager: 10.0.0.10
  Server Status: available
```

## Key IDs

```
-----
000000000000000000002000000000001001d71f3b2468d7e16a6e6972d3e664520000000000000000
000000000000000000002000000000005004d03aca5b72cd20b2f83eae1531c605e0000000000000000
```

The following loads any keys that exist on the key servers with IP address 10.0.0.10 with key-tag "node1" that are not currently stored in key tables of the nodes in the cluster. In this example, a key with that key-tag was missing from two nodes in the cluster:

```
cluster-1::> security key-manager restore -address 10.0.0.10 -key-tag node1
Node: node1
  Key Manager: 10.0.0.10
  Server Status: available

Key IDs

Node: node2
  Key Manager: 10.0.0.10
  Server Status: available

Key IDs
-----
000000000000000000002000000000001001d71f3b2468d7e16a6e6972d3e664520000000000000000
```

## Related Links

- [security key-manager external restore](#)

# security key-manager setup

(DEPRECATED)-Configure key manager connectivity

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command is deprecated and might be removed in a future release. To set up external key manager, use `security key-manager external enable`, and to set up the Onboard Key Manager use `security key-manager onboard enable` instead.

The `security key-manager setup` command enables you to configure key management. Data ONTAP supports two mutually exclusive key management methods: external via one or more key management interoperability protocol (KMIP) servers, or internal via an Onboard Key Manager. This command is used to configure an external or internal key manager. When configuring an external key management server, this command records networking information on all node that is used during the boot process to retrieve keys needed for booting from the KMIP servers. For the Onboard Key Manager, this command prompts you to configure a passphrase to protect internal keys in encrypted form.

This command can also be used to refresh missing onboard keys. For example, if you add a node to a cluster that has the Onboard Key Manager configured, you will run this command to refresh the missing keys.

For the Onboard Key Manager in a MetroCluster configuration, if the `security key-manager update-passphrase` command is used to update the passphrase on one site, then run the `security key-manager setup` command with the new passphrase on the partner site before proceeding with any key-manager operations.

## Parameters

### `[-node <nodename>]` - Node Name

This parameter is used only with the Onboard Key Manager when a refresh operation is required (see command description). This parameter is ignored when configuring external key management and during the initial setup of the Onboard Key Manager.

### `[-cc-mode-enabled {yes|no}]` - Enable Common Criteria Mode?

When configuring the Onboard Key Manager, this parameter is used to specify that Common Criteria (CC) mode should be enabled. When CC mode is enabled, you will be required to provide a cluster passphrase that is between 64 and 256 ASCII character long, and you will be required to enter that passphrase each time a node reboots.

### `[-sync-metrocluster-config {yes|no}]` - Sync MetroCluster Configuration from Peer

When configuring the Onboard Key Manager in a MetroCluster configuration, this parameter is used to indicate that the `security key-manager setup` command has been performed on the peer cluster, and that the `security key-manager setup` command on this cluster should import the peer's configuration.

### `[-are-unencrypted-metadata-volumes-allowed-in-cc-mode {yes|no}]` - Are Unencrypted Metadata Volumes Allowed in CC-Mode

If Common Criteria (CC) mode is enabled this parameter allows unencrypted metadata volumes to exist. These metadata volumes are created internally during normal operation. Examples are

volumes created during SnapMirror and Vserver migrate operations. The default value is **no**.

## Examples

The following example creates a configuration for external key management:

```
cluster-1::> security key-manager setup
Welcome to the key manager setup wizard, which will lead you through
the steps to add boot information.

Enter the following commands at any time
"help" or "?" if you want to have a question clarified,
"back" if you want to change your answers to previous questions, and
"exit" if you want to quit the key manager setup wizard. Any changes
you made before typing "exit" will be applied.

Restart the key manager setup wizard with "security key-manager setup". To
accept a default or omit a question, do not enter a value.

Would you like to configure the Onboard Key Manager? {yes, no} [yes]: no
Would you like to configure the KMIP server environment? {yes, no} [yes]: yes
```

The following example creates a configuration for the Onboard Key Manager:

```
cluster-1::> security key-manager setup
Welcome to the key manager setup wizard, which will lead you through
the steps to add boot information.

Enter the following commands at any time
"help" or "?" if you want to have a question clarified,
"back" if you want to change your answers to previous questions, and
"exit" if you want to quit the key manager setup wizard. Any changes
you made before typing "exit" will be applied.

Restart the key manager setup wizard with "security key-manager setup". To
accept a default or omit a question, do not enter a value.

Would you like to configure the Onboard Key Manager? {yes, no} [yes]: yes
Enter the cluster-wide passphrase for the Onboard Key Manager. To continue the
configuration, enter the passphrase, otherwise type "exit":
Re-enter the cluster-wide passphrase:
After configuring the Onboard Key Manager, save the encrypted configuration data
in a safe location so that you can use it if you need to perform a manual recovery
operation. To view the data, use the "security key-manager backup show" command.
```

The following example creates a configuration for the Onboard Key Manager with Common Criteria mode enabled:

```
cluster-1::> security key-manager setup -cc-mode-enabled yes
Welcome to the key manager setup wizard, which will lead you through
the steps to add boot information.
```

Enter the following commands at any time  
"help" or "?" if you want to have a question clarified,  
"back" if you want to change your answers to previous questions, and  
"exit" if you want to quit the key manager setup wizard. Any changes  
you made before typing "exit" will be applied.

Restart the key manager setup wizard with "security key-manager setup". To  
accept a default or omit a question, do not enter a value.

```
Would you like to configure the Onboard Key Manager? {yes, no} [yes]: yes
Enter the cluster-wide passphrase for the Onboard Key Manager. To continue the
configuration, enter the passphrase, otherwise type "exit":
Re-enter the cluster-wide passphrase:
After configuring the Onboard Key Manager, save the encrypted configuration data
in a safe location so that you can use it if you need to perform a manual recovery
operation. To view the data, use the "security key-manager backup show" command.
```

# security key-manager show-key-store

Displays the configured key manager key stores.

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command displays the list of configured key managers.

## Parameters

{ [-fields <fieldname>, ...]

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[[-instance ]]**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-vserver <vserver name>] - Vserver**

If you specify this parameter, then the command will list the key manager configured for the given Vserver.

**[-key-store <Key Store>] - Key Store**

If you specify this parameter, then the command displays only the vservers that have the given key-store configured.

**[-state <Key Store state>] - Key Store State**

If you specify this parameter, then the command displays only the vservers that have the given state configured.

**[-keystore-type <Key Store Type>] - Key Store Type (Azure/AWS etc)**

If you specify this parameter, then the command displays only the vservers that have the given keystore-type configured. This parameter is used to specify a particular type of external key manager. If this parameter is specified and 'key-store' is provided as 'onboard', the "security key-manager show-key-store" command will not return any entries.

**[-policy <text>] - Key Manager Policy Name**

If you specify this parameter, then the command displays only the vservers that have the given policy.

## Examples

The following example shows all configured key managers in the cluster. In the example, the admin vserver has the Onboard Key Manager configured and the data vserver "datavs1" has external key management configured:

```
cluster-1::> security key-manager show-key-store
```

Vserver	Key Store	Key Store Type
cluster-1	onboard	-
datavs1	external	AKV

## security key-manager show

(DEPRECATED)-Display key management servers

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command is deprecated and may be removed in a future release. Use [security key-manager external show](#) instead.

This command displays the key management servers configured on the cluster. This command is not supported when the Onboard Key Manager is enabled.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[ -status ]**

If you specify this parameter, the command displays the status of each key management server.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[ -node {<nodename>|local} ] - Node**

This parameter specifies the name of the node that you want to retrieve key management server status for. If parameter is not specified, all nodes will retrieve the key management servers status.

**[ -address <IP Address> ] - IP Address**

Shows only a key management server registered with the input address. It is also possible to show multiple key management servers.

**[ -server-port <integer> ] - Server TCP Port**

If you specify this parameter, the command displays only key servers listening on this port.

## Examples

The following example lists all configured key management servers:

```
cluster-1::> security key-manager show

Node                Registered Key Manager
-----
node1               10.225.89.33
node2               10.225.89.33
```

The following example lists all configured key management servers, the TCP port on which those servers are expected to listen for incoming KMIP connections, and their server status:

```
cluster-1::> security key-manager show -status
```

Node	Port	Registered Key Manager	Status
node1	5696	10.225.89.33	available
node2	5696	10.225.89.33	available

## Related Links

# security key-manager update-passphrase

(DEPRECATED)-Update cluster-wide passphrase

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command is deprecated and might be removed in a future release. Use [security key-manager onboard update-passphrase](#) instead.

The **security key-manager update-passphrase** command provides a way to update the cluster-wide passphrase, created initially by running the [security key-manager setup](#) command, that is used for the Onboard Key Manager. This command prompts for the existing passphrase, and if that passphrase is correct then the command prompts for a new passphrase.

When the **security key-manager update-passphrase** command is executed in a MetroCluster configuration, then run the [security key-manager setup](#) command with the new passphrase on the partner site before proceeding with any key-manager operations. This allows the updated passphrase to be replicated to the partner site.

## Examples

The following example updates the cluster-wide passphrase used for the Onboard Key Manager:

```
cluster-1::*> security key-manager update-passphrase
```

```
Warning: This command will reconfigure the cluster passphrase for the Onboard  
Key Manager.
```

```
Do you want to continue? {y|n}: y
```

```
Enter current passphrase:
```

```
Enter new passphrase:
```

Reenter the new passphrase:  
 Update passphrase has completed. Save the new encrypted configuration data in a safe location so that you can use it if you need to perform a manual recovery operation. To view the data, use the "security key-manager backup show" command.

## Related Links

- [security key-manager onboard update-passphrase](#)
- [security key-manager setup](#)

# security key-manager backup show

(DEPRECATED)-Show salt and wrapped keys as a hex dump

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command is deprecated and might be removed in a future release. Use [security key-manager onboard show-backup](#) instead.

This command displays the backup information for the Onboard Key Manager, which would be used to recover the cluster in case of catastrophic situations. The information displayed is for the cluster as a whole (not individual nodes). This command is not supported for an external key management configuration.

## Examples

The following example displays the Onboard Key Manager backup data for the cluster:

```
cluster-1::> security key-manager backup show

# security key-manager config modify

Modify key management configuration options

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command modifies the key management configuration options.

## Parameters

### **[`-cc-mode-enabled` {`true`|`false`}] - Enable Common Criteria Mode**

This parameter modifies the configuration state of the Onboard Key Manager (OKM) Common Criteria (CC) mode. CC mode enforces some of the policies required by the Common Criteria "Collaborative Protection Profile for Full Drive Encryption-Authorization Acquisition" (FDE-AA cPP) and "Collaborative Protection Profile for Full Drive Encryption-Encryption Engine" documents.

### **[`-health-monitor-polling-interval` <`integer`>] - Health Monitor Polling Period (in minutes)**

This parameter modifies the the polling interval of the keyserver health monitor at the cluster level.

**[-cloud-kms-retry-count <integer>] - Cloud KMS connection retry count**

This parameter modifies the the cloud keymanager connection retry count at the cluster level.

**[-are-unencrypted-metadata-volumes-allowed-in-cc-mode {true|false}] - Are Unencrypted Metadata Volumes Allowed in Common Criteria Mode**

If Common Criteria (CC) mode is enabled this parameter allows unencrypted metadata volumes to exist. These metadata volumes are created internally during normal operation. Examples are volumes created during SnapMirror and Vserver migrate operations. The default value is **false** .

## Examples

The following command enables Common Criterial mode in the cluster:

```
cluster-1::*> security key-manager config modify -cc-mode-enabled true
```

The following command modifies the keyserver health monitor polling interval to be 30 minutes:

```
cluster-1::*> security key-manager config modify -health-monitor-polling-interval 30
```

The following command modifies the cloud keymanager connection retry count to 3:

```
cluster-1::*> security key-manager config modify -cloud-kms-retry-count 3
```

# security key-manager config show

Display key management configuration options

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command displays the key management configuration options.

The "cc-mode-enabled" option reflects the current configuraton state for Common-Criteria (CC) mode for the Onboard Key Manager. CC mode is an operational mode that enforces some of the policies required by the Common Criteria "Collaborative Protection Profile for Full Drive Encryption-Authorization Acquisition" (FDE-AA cPP) and "Collaborative Protection Profile for Full Drive Encryption-Encryption Engine" documents. The feature can be enabled when the Onboard Key Manager is configured using the [security key-manager setup](#) command or after the Onboard Key Manager is configured using the [security key-manager config modify](#) command.

## Examples

The following example displays the state of all key-manager configuration options:

```
cluster-1::*> security key-manager config show
CC-Mode health-monitor-polling-interval cloud-kms-retry-count
Enabled (in minutes)
-----
true 30 0
```

## Related Links

- [security key-manager config modify](#)

# security key-manager external add-servers

Add external key management servers

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command adds the key management servers of the given hosts and ports to the given Vserver's external key manager's list of four possible key management servers. When adding key management servers to the external key manager associated with the admin Vserver, you must run the same command specifying the same set of key servers on the peer cluster. When adding key management servers to a data Vserver, you can run the **security key-manager external add-servers** command on the active cluster only, as the command is replicated to the peer cluster. However, you need to ensure that the key management servers specified are reachable from both clusters. This command is not supported if external key management is not enabled for the Vserver. Use this command to add primary key servers. To modify the list of secondary key servers associated with a primary key server, use the [security key-manager external modify-server](#) command.

## Parameters

**-vserver <vserver name> - Vserver Name**

Use this parameter to specify the Vserver on which to add the key management servers.

**-key-servers <Hostname and Port>, ... - External Key Management Servers**

Use this parameter to specify the list of additional key management servers that the external key manager uses to store keys.

## Examples

The following example adds two key management servers to the list of servers used by the external key manager for Vserver cluster-1. The first key management server's hostname is keyserver1.local and is listening on the default port 5696, and the second key management server's IP is 10.0.0.20 and is listening on port 15696:

```
cluster-1::> security key-manager external add-servers -vserver cluster-1 -key-servers
keyserver1.local, 10.0.0.20:15696
```

## Related Links

- [security key-manager external modify-server](#)

# security key-manager external disable

Disable external key management

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

This command disables the external key manager associated with the given Vserver. If the key manager is in use by ONTAP, you cannot disable it. When disabling the external key manager associated with the admin Vserver, you must run the same command on the peer cluster. When disabling the external key manager for a data Vserver, you can run the **security key-manager external disable** command on the active cluster only, as the command is replicated on the peer cluster. This command is not supported when the Onboard Key Manager is enabled for the given Vserver.

## Parameters

**-vserver <vserver name> - Vserver Name**

Use this parameter to specify the Vserver on which the external key manager is to be disabled.

## Examples

The following example removes the external key manager for Vserver cluster-1:

```
cluster-1::*> security key-manager external disable -vserver cluster-1
Warning: This command will permanently delete the external key management
configuration for Vserver "cluster-1".
```

```
Do you want to continue? {y|n}: y
```

# security key-manager external enable

Enable external key management

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command enables the external key manager associated with the given Vserver. This command is not supported when a key manager for the given Vserver is already enabled. When enabling the external key manager associated with the admin Vserver, you must run the same command specifying the same set of key servers on the peer cluster. When enabling the external key manager for a data Vserver, you can run the **security key-manager external enable** command on the active cluster only, as the configuration will be replicated on the peer cluster. However, you must ensure that the key management servers specified in the **security key-manager external enable** command are reachable from both clusters. Only primary key servers can be added using this command.

## Parameters

**-vserver <vserver name> - Vserver Name**

Use this parameter to specify the Vserver on which the external key manager is to be enabled.

**-key-servers <Hostname and Port>, ... - List of External Key Management Servers**

Use this parameter to specify the list of up to four key management servers that the external key manager uses to store keys.

**-client-cert <text> - Name of the Client Certificate**

Use this parameter to specify the unique name of the client certificate that the key management servers use to ensure the identity of Data ONTAP.

**-server-ca-certs <text>, ... - Names of the Server CA Certificates**

Use this parameter to specify the unique names of server-ca certificates that Data ONTAP uses to ensure the identify of the key management servers.

**[-policy <text>] - Key Manager Policy**

Use this parameter to specify a specific key manager security policy to be used by this key manager.

## Examples

The following example enables the external key manager for Vserver cluster-1. The command includes three key management servers. The first key server's hostname is ks1.local and is listening

on port 15696. The second key server's IP address is 10.0.0.10 and is listening on the default port 5696. The third key server's IPv6 address is fd20:8b1e:b255:814e:32bd:f35c:832c:5a09, and is listening on port 1234.

```
cluster-1::> security key-manager external enable -vserver cluster-1 -key-servers
ks1.local:15696,10.0.0.10,[fd20:8b1e:b255:814e:32bd:f35c:832c:5a09]:1234 -client-cert
AdminVserverClientCert -server-ca-certs ServerCaCert1,ServerCaCert2
```

## security key-manager external modify-server

Modify key server properties

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

### Description

This command modifies configuration information for configured key management servers. When modifying a key management server from the external key manager associated with the admin Vserver, you must run the same command specifying the same set of parameters on the peer cluster. When modifying a key management server from a data Vserver, you can run the **security key-manager external modify-server** command on the active cluster only as the command is replicated on the peer cluster. However, if the password associated with a key management server is modified, then you must run the **security key-manager external modify-server** command specifying the same password on the peer cluster as the password is not replicated between clusters. This command is supported only when external key manager has been enabled for the given Vserver.

### Parameters

**-vserver <vserver name> - Vserver Name**

Use this parameter to specify the Vserver on which to modify the key management server configuration.

**-key-server <Hostname and Port> - External Key Server**

Use this parameter to specify the primary key management server for which the command modifies the configuration.

**[-secondary-key-servers <Remote InetAddress>, ...] - Secondary Key Servers**

Use this parameter to specify the secondary key management servers that will be members of the set of clustered key servers. When specifying a secondary key server, a port number cannot be associated with the secondary key server.

**[-timeout <integer>] - Key Server I/O Timeout**

Use this parameter to specify the I/O timeout, in seconds, for the selected key management server.

**[-username <text>] - Authentication User Name**

Use this parameter to specify the username with which Data ONTAP authenticates with the key management server.

## Examples

The following example modifies the I/O timeout to 45 seconds for Vserver cluster-1, key server keyserver1.local:

```
cluster-1::> security key-manager external modify-server -vserver cluster-1 -key
-server keyserver1.local -timeout 45
```

The following example modifies the username and passphrase used to authenticate with key server keyserver1.local:

```
cluster-1::> security key-manager external modify-server -vserver cluster-1 -key
-server keyserver1.local -username ksuser
Enter the password:
Reenter the password:
```

The following example modifies the secondary key management servers secondarykeyserver1.local and secondarykeyserver2.local to be in a cluster configuration with the primary key management server keyserver1.local

```
cluster-1::> security key-manager external modify-server -vserver cluster-1 -key
-server keyserver1.local -secondary-key-servers
secondarykeyserver1.local,secondarykeyserver2.local
```

# security key-manager external modify

Modify external key management

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command modifies the external key manager configuration associated with the given Vserver. When modifying the external key manager configuration associated with the admin Vserver, you must run the same command specifying the same parameters on the peer cluster. When modifying the external key manager configuration associated with a data Vserver, you can run the **security key-manager external modify** command on the active cluster only as the configuration modifications are replicated on the peer cluster. This command is not supported when external key management is

not enabled for the given Vserver.

## Parameters

### **-vserver <vserver name> - Vserver Name**

Use this parameter to specify the Vserver on which the key manager to be modified is located.

### **[-client-cert <text>] - Name of the Client Certificate**

Use this parameter to modify the name of the client certificate that the key management servers use to ensure the identity of Data ONTAP. If the keys of the new certificate do not match the keys of the existing certificate, or if the TLS connectivity with key-management servers fails with the new certificate, the operation fails. Running this command in the diagnostic privilege mode ignores failures and allows the command to complete.

### **[-server-ca-certs <text>,...] - Names of the Server CA Certificates**

Use this parameter to modify the names of server-ca certificates that Data ONTAP uses to ensure the identity of the key management servers. Note that the list provided completely replaces the existing list of certificates. If the TLS connectivity with key-management servers fails with the new list of server-ca certificates, the operation fails. Running this command in the diagnostic privilege mode ignores failures and allows the command to complete.

## Examples

The following example updates the client certificate used with the key management servers:

```
cluster-1::> security key-manager external modify -vserver cluster-1 -client-cert  
NewClientCert
```

# security key-manager external remove-servers

Remove external key management servers

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command removes the key management servers at the given hosts and ports from the given Vserver's external key manager's list of key management servers. If any of the specified key management servers is the sole storage location for any key that is in use by Data ONTAP, then you are unable to remove the key server. When removing key management servers from the external key manager associated with the admin Vserver, you must run the same command specifying the same set of key servers on the peer cluster. When removing key management servers from a data Vserver, you can run the **security key-manager external remove-servers** command on the active cluster only

as the the command is replicated on the peer cluster. This command is not supported when external key management is not enabled for the given Vserver. Use this command is remove primary key servers. To modify the list of secondary key servers associated with a primary key server, use the [security key-manager external modify-server](#) command.

## Parameters

### **-vserver <vserver name> - Vserver Name**

Use this parameter to specify the Vserver on which the external key manager is to be removed.

### **-key-servers <Hostname and Port>,... - External Key Management Servers**

Use this parameter to specify the list of key management servers that you want to remove from the external key manager.

### **[-force {true|false}] - Bypass OOQ Check?**

Set this parameter to true to bypass checks for out of quorum nodes.

## Examples

The following example removes the key management server keyserver1.local, listening on the default port of 5696 and the key management server at IP 10.0.0.20, listening on port of 15696.

```
cluster-1::*> security key-manager external remove-servers -vserver cluster-1
-key-servers keyserver1.local,10.0.0.20:15696
```

## Related Links

- [security key-manager external modify-server](#)

# security key-manager external restore

Restore the key ID pairs from the key management servers.

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command retrieves and restores any current unrestored keys associated with the storage controller from the specified key management servers. When restoring keys from the external key manager associated with the admin Vserver, you must run the same command on the peer cluster. When restoring keys from a data Vserver, you can run the **security key-manager external restore** command on the active cluster only as the command is replicated on the peer cluster. This command is not supported when external key management has not been enabled for the Vserver.

This command only restores keys from primary key servers.

## Parameters

### { [-fields <fieldname>, ... ] }

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

### [ [-instance ] ] }

If you specify the **-instance** parameter, the command displays detailed information about all fields.

### [-node {<nodename>|local}] - Node

This parameter specifies the name of the node that will load unrestored key IDs into its internal key table. If not specified, all nodes retrieve unrestored keys into their internal key table.

### [-vserver <vserver name>] - Vserver Name

This parameter specifies the Vserver for which to list the keys. If not specified, this command restores key for all Vservers.

### [-key-server <Hostname and Port>] - Key Server

If this parameter is specified, this command restores keys from the key management server identified by the host and port. If not specified, this command restores keys from all available key management servers.

### [-key-id <Hex String>] - Key ID

If you specify this parameter, then the command restores only the key IDs that match the specified value.

### [-key-tag <text>] - Key Tag

If you specify this parameter, then the command restores only the key IDs that match the specified key-tag. The key-tag for Volume Encryption Keys (VEKs) is set to the UUID of the encrypted volume. If not specified, all key ID pairs for any key tags are restored.

## Examples

The following command restores keys that are currently on a key server but are not stored within the key tables on the cluster. One key is missing for vservers cluster-1 on node1, and another key is missing for vservers datavms on node1 and node2:

```
cluster-1::> security key-manager external restore
Node: node1
      Vserver: cluster-1
      Key Server: 10.0.0.1:5696
```

```
Key ID

## security key-manager external show-status

Show the set of configured external key management servers

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

### Description

This command displays connectivity information between Data ONTAP nodes and configured external key management servers.

### Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[ [-instance ] ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node Name**

If you specify this parameter, then the command displays the connectivity information for only the given node.

**[-vserver <vserver name>] - Vserver Name**

If you specify this parameter, then the command displays the key management servers for only the given Vserver.

**[-key-server <Hostname and Port>] - Primary Key Server**

If you specify this parameter, then the command displays the connectivity information for only the key management servers with the given primary key server host name or IP address listening on the given port.

**[-key-server-status {available|not-responding|unknown}] - Key Server Status**

If you specify this parameter, then the command displays the connectivity information for only the key management servers with the given status.

**[-status-details <text>] - Key Server Status Details**

If you specify this parameter, then the command displays the connectivity information for only the key management servers with the given status details.

**[-secondary-key-servers <text>, ...] - Secondary Key Servers**

If you specify this parameter, then the command displays the connectivity information of only the primary key management servers that have the given secondary key management servers.

## Examples

The following example lists all configured key management servers for all Vservers:

```
cluster-2::*> security key-manager external show-status
```

Node	Vserver	Primary Key Server	Status
node1	datavs	keyserver.datavs.com:5696 Secondary Servers: ks1.local	available
	cluster-1	10.0.0.10:5696 fd20:8b1e:b255:814e:32bd:f35c:832c:5a09:1234	available available
node2	datavs	keyserver.datavs.com:5696 Secondary Servers: ks1.local	available
	cluster-1	10.0.0.10:5696 fd20:8b1e:b255:814e:32bd:f35c:832c:5a09:1234	available available

8 entries were displayed.

## security key-manager external show

Show the set of configured external key management servers.

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege

level.

## Description

This command displays the external key management servers configured on the cluster for a given Vserver. No entries are displayed when external key management is not enabled for the given Vserver. This command displays the primary external key management servers, along with any associated secondary key servers, configured on the cluster for a given Vserver.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-vserver <vserver name>] - Vserver Name**

If you specify this parameter, then the command displays only the key management servers for the given Vserver.

**[-key-server <text>] - Key Server Name with port**

If you specify this parameter, then the command displays only the key management servers with the given primary key server host name or IP address listening on the given port.

**[-client-cert <text>] - Name of the Client Certificate**

If you specify this parameter, then the command displays only the key management servers using a client certificate with the given name.

**[-server-ca-certs <text>, ... ] - Names of the Server CA Certificates**

If you specify this parameter, then the command displays only the key management servers using server-ca certificates with the given names.

**[-timeout <integer>] - Server I/O Timeout**

If you specify this parameter, then the command displays only the key management servers using the given I/O timeout.

**[-username <text>] - Authentication User Name**

If you specify this parameter, then the command displays only the key management servers using the given authentication username.

**[-policy <text>] - Security Policy**

If you specify this parameter, then the command displays only the key management servers using the given key manager policy.

**[-secondary-key-servers <text>,...] - Secondary Key Servers**

If you specify this parameter, then the command displays only the key management servers with the given secondary key servers.

**Examples**

The following example lists all configured key management servers for all Vservers:

```
cluster-1::> security key-manager external show
Vserver: datavs
  Client Certificate: datavsClientCert
  Server CA Certificates: datavsServerCaCert1, datavsServerCaCert2
  Security Policy: IBM_Key_Lore

Primary Key Server
-----
keyserver.datavs.com:5696
Vserver: cluster-1
  Client Certificate: AdminClientCert
  Server CA Certificates: AdminServerCaCert
  Security Policy:
Primary Key Server
-----
10.0.0.10:1234
  Secondary Servers: ks1.local, ks2.local
fd20:8b1e:b255:814e:32bd:f35c:832c:5a09:1234
ks1.local:1234
4 entries were displayed.
```

The following example lists all configured key management servers with more detail, including timeouts and usernames:

```
cluster-1::> security key-manager external show -instance
Vserver: datavs
  Client Certificate: datavsClientCert
  Server CA Certificates: datavsServerCaCert1, datavsServerCaCert2
  Primary Key Server: keyserver.datavs.com:5696
    Timeout: 25
    Username: datavsuser
  Security Policy: IBM_Key_Lore
  Secondary Key Servers:
Vserver: cluster-1
  Client Certificate: AdminClientCert
  Server CA Certificates: AdminServerCaCert
  Primary Key Server: 10.0.0.10:1234
    Timeout: 25
    Username:
  Security Policy:
```

```

Secondary Key Servers: ks1.local, ks2.local
Vserver: cluster-1
  Client Certificate: AdminClientCert
  Server CA Certificates: AdminServerCaCert
  Primary Key Server: fd20:8b1e:b255:814e:32bd:f35c:832c:5a09:1234
    Timeout: 25
    Username:
    Security Policy:
  Secondary Key Servers:
Vserver: cluster-1
  Client Certificate: AdminClientCert
  Server CA Certificates: AdminServerCaCert
  Primary Key Server: ks1.local:1234
    Timeout: 45
    Username:
    Security Policy:
  Secondary Key Servers:
4 entries were displayed.

```

## security key-manager external aws check

Show detailed status of the AWS KMS configurations

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

### Description

This command displays the Amazon Web Service (AWS) Key Management Service (KMS) status.

### Parameters

**{ [-fields <fieldname>,...]**

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[-instance ]}**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node**

If this parameter is specified then the command displays only the AWS KMS status for the given node.

**[-vserver <Vserver Name>] - Vserver Name**

If this parameter is specified then the command displays only the AWS KMS status for the given

Vserver.

### **[-category <Categories for Cloud KMS status check>] - Component**

If this parameter is specified then the command displays only the AWS KMS status for the given category.

Category	Description
-----	-----
service_reachability	Cloud KMS Reachability
ekmip_server	Embedded KMIP Server Reachability
kms_wrapped_key_status	Status of KMS Wrapped Keys On Cluster

### **[-status <Status Check>] - Status**

If this parameter is specified then the command displays only the AWS KMS status entries matching the given status.

```
OK
FAILED
UNKNOWN
```

### **[-detail <text>] - Status Details**

This field displays a detailed status message, if available.

## Examples

The example below displays the status of all components of all AWS KMS instances configured on node vsim1.

```
cluster-1::> security key-manager external aws check -node vsim1
Vserver: vs1
Node: vsim1

Category: service_reachability
          Status: OK

Category: ekmip_server
          Status: OK

Category: kms_wrapped_key_status
          Status: OK
```

# security key-manager external aws disable

Disable AWS KMS

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

This command disables the Amazon Web Service Key Management Service (AWSKMS) associated with the given Vserver. AWSKMS cannot be disabled if it is in use by ONTAP. This command will fail if AWSKMS has not been enabled for the Vserver.

## Parameters

**-vserver <Vserver Name> - Vserver**

Use this parameter to specify the Vserver on which the AWSKMS is to be disabled.

## Examples

The following example disables the AWSKMS for Vserver v1.

```
cluster-1::>security key-manager external aws disable -vserver v1
```

# security key-manager external aws enable

Enable AWS KMS

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command enables the Amazon Web Service Key Management Service (AWSKMS) associated with the given Vserver. An AWS project and AWSKMS must be deployed on the AWS portal prior to running this command. AWSKMS can only be enabled on a data Vserver that doesn't already have a key manager configured. AWSKMS cannot be enabled in a MetroCluster environment.

## Parameters

**-vserver <Vserver Name> - Vserver**

Use this parameter to specify the Vserver on which the AWSKMS is to be enabled.

**-region <text> - AWS KMS Region**

Use this parameter to specify the region of the deployed AWS project.

**-key-id <text> - AWS Key Id**

Use this parameter to specify the key ID of the deployed AWS project.

**[-access-key-id <text>] - AWS Access Key ID**

Use this parameter to specify the access key ID of the deployed AWS project.

**[-encryption-context <text>] - Additional Layer of Authentication and Logging**

Use this parameter to specify the encryption context to satisfy AWS grant constraint if it is configured.

## Examples

The following example enables the AWSKMS for Vserver v1. The parameters in the example command identify an Amazon Web Service (AWS) project application deployed on the AWS. The AWS project application has a region "test\_na\_region", a key ID "test\_KEYID" and an access key ID "test\_accessKeyID".

```
cluster-1::*> security key-manager external aws enable -vserver v1 -region  
test_na_region -key-id test_KEYID -access-key-id test_accessKeyID
```

Enter the Amazon Web Service Key Management Service secret access key: Press <Enter>  
when done

# security key-manager external aws rekey-external

Rekey an external key of the Vserver

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command replaces the existing AWS KMS key encryption key (KEK) and results in the key hierarchy being protected by the new user specified AWS KMS KEK. Prior to running this command, the user should have already made the necessary changes on the AWS KMS Portal to use the new KEK. Upon successful completion of this command, the internal keys for the given Vserver will be protected by the new AWS KMS KEK.

## Parameters

**-vserver <Vserver Name> - Vserver**

This parameter specifies the Vserver for which ONTAP should rekey the AWS KMS KEK

**-key-id <text> - AWS Key ID**

This parameter specifies the key ID of the new AWS KMS KEK that should be used by ONTAP for the provided Vserver. In the case of automatic AWS KMS KEK rotation, the key ID will be the

identifier of the user's already existing AWS KMS Customer Managed Key (CMK). In the case of manual AWS KMS KEK rotation, the key ID will be the identifier of the user's new AWS KMS CMK.

## Examples

The following command rekeys the AWS KMS KEK for data Vserver vs1 using a new key-id key3.

```
cluster-1::> security key-manager external aws rekey-external -vserver vs1 -key-id key3
```

# security key-manager external aws rekey-internal

Rekey an internal key of the Vserver

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

This command updates the internal Vserver key hierarchy by rekeying the top-level internal key encryption key (KEK). Upon successful completion of the command, all keys in the Vserver key hierarchy will be protected by the new top-level KEK.

## Parameters

**-vserver <Vserver Name> - Vserver**

This parameter specifies the Vserver for which ONTAP should rekey the top-level KEK

## Examples

The following command rekeys the top-level KEK for data Vserver vs1.

```
cluster-1::> security key-manager external aws rekey-internal -vserver vs1
```

# security key-manager external aws restore

Restore missing keys of AWS KMS

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command retrieves and restores any unrestored keys associated with the given Vserver to each node's internal key tables.

## Parameters

**-vserver <Vserver Name> - Vserver**

This parameter specifies the Vserver to which the missing keys will be restored.

## Examples

The following command restores missing keys for the data Vserver v1 (which has AWSKMS enabled) to the internal key tables on each node in the cluster.

```
cluster-1::> security key-manager external aws restore -vserver v1
```

# security key-manager external aws show

Display AWS KMS configuration

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command displays the Amazon Web Service Key Management Service (AWSKMS) configuration for a given Vserver.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-vserver <Vserver Name>] - Vserver**

If you specify this parameter, then the command displays only the AWSKMS configuration for the given Vserver.

**[-region <text>] - AWS KMS Region**

If you specify this parameter, then the command displays only the AWSKMS configuration with the given region.

**[-key-id <text>] - AWS Key ID**

If you specify this parameter, then the command displays only the AWSKMS configuration with the given key-id.

**[-access-key-id <text>] - AWS Access Key ID**

If you specify this parameter, then the command displays only the AWSKMS configuration with the given access key ID.

**[-service <text>] - AWS Service Type**

If you specify this parameter, then the command displays only the AWSKMS configurations with the given AWS service type.

**[-default-domain <text>] - AWS KMS Default Domain**

If you specify this parameter, then the command displays only the AWSKMS configurations with the given AWS KMS default domain.

**[-state {available|not-responding|unknown}] - AWS KMS Cluster State**

If you specify this parameter, then the command displays only the AWSKMS configurations with the given state. The state can be either available or unknown.

**[-unavailable-nodes <text>] - Names of Unavailable Nodes**

If you specify this parameter, then the command displays only the AWSKMS configurations with the given unavailable-nodes.

**[-polling-period <integer>] - Polling period (in minutes)**

If you specify this parameter, then the command displays only the AWSKMS configurations with the given polling period.

**[-port <integer>] - AWS KMS Port**

If you specify this parameter, then the command displays only the AWSKMS configurations with the given AWS KMS port.

**[-verify {true|false}] - Verify the AWS KMS Host**

If you specify this parameter, then the command displays only the AWSKMS configurations with the given value of the verify flag.

**[-verify-host {true|false}] - Verify the AWS KMS Host's Hostname**

If you specify this parameter, then the command displays only the AWSKMS configurations with the given value of the verify-host flag.

**[-verify-ip {true|false}] - Verify the AWS KMS Host's IP**

If you specify this parameter, then the command displays only the AWSKMS configurations with the given value of the verify-ip flag.

**[-host <text>] - AWS KMS Host Name**

If you specify this parameter, then the command displays only the AWSKMS configurations with the given AWS KMS host name.

**[-encryption-context <text>] - Additional Layer of Authentication and Logging**

If you specify this parameter, then the command displays only the AWSKMS configurations with the given value of the AWS encryption-context.

## Examples

The following example lists all AWSKMS configurations.

```
cluster-1::>security key-manager external aws show
      Vserver: SAMPLE_VSERVER
      Region: SAMPLE_NA_REGION

Access Key Id                               State
-----
SAMPLE_ACCESS_KEY_ID                       unknown
Unavailable Nodes:                         node1
```

# security key-manager external aws update-credentials

Update AWS secret access key and access key ID

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

This command allows the user to update the secret access key which is used by the Amazon Web Service Key Management Service (AWSKMS) configured for the given Vserver. The secret access key is initially set by running the security key-manager external aws enable command. This command will fail if AWSKMS has not been enabled for the Vserver.

## Parameters

**-vserver <Vserver Name> - Vserver**

Use this parameter to specify the Vserver for which the AWSKMS secret access key will be updated.

**-access-key-id <text> - Access Key ID**

Use this parameter to specify the new access key id of the updated credentials.

**[-skip-verify {true|false}] - Don't verify user credentials**

Set this parameter to true to skip verification of the updated credentials.

## Examples

The following example updates the AWSKMS secret access key for Vserver v1.

```
cluster-1::> security key-manager external aws update-credentials -vserver v1
```

Enter the new secret access key: Press <Enter> when done

# security key-manager external azure check

Show detailed status of the Azure Key Vault configurations

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

This command displays the Azure Key Vault (AKV) Key Management Service (KMS) status.

## Parameters

**{ [-fields <fieldname>,...]**

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[-instance ]}**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node**

If this parameter is specified then the command displays only the AKV status for the given node.

**[-vserver <Vserver Name>] - Vserver Name**

If this parameter is specified then the command displays only the AKV status for the given Vserver.

**[-category <Categories for Cloud KMS status check>] - Component**

If this parameter is specified then the command displays only the AKV status for the given category.

Category	Description
-----	-----
service_reachability	Cloud KMS Reachability
ekmip_server	Embedded KMIP Server Reachability
kms_wrapped_key_status	Status of KMS Wrapped Keys On Cluster

**[-status <Status Check>] - Status**

If this parameter is specified then the command displays only the AKV status entries matching the given status.

OK  
FAILED  
UNKNOWN

**[-detail <text>] - Status Details**

This field displays the detailed status message, if available.

## Examples

The example below displays the status of all components of all AKV KMS configured on the node.

```
cluster-1::> security key-manager external azure check -node vsim1
Vserver: vs1
Node: vsim1

Category: service_reachability
          Status: OK

Category: ekmip_server
          Status: OK

Category: kms_wrapped_key_status
          Status: OK
```

# security key-manager external azure disable

## Disable Azure Key Vault

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

This command disables the Azure Key Vault (AKV) associated with the given Vserver. If the AKV is in use by ONTAP, you cannot disable it. This command is not supported if AKV has not been enabled for the Vserver.

## Parameters

**-vserver <Vserver Name> - Vserver**

Use this parameter to specify the Vserver on which the AKV is to be disabled.

## Examples

The following example disables the AKV for Vserver v1.

```
cluster-1::>security key-manager external azure disable -vserver v1
```

# security key-manager external azure enable

Enable Azure Key Vault

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command enables the Azure Key Vault (AKV) associated with the given Vserver. An Azure application and AKV must be deployed on the Azure portal prior to running this command. This command is not supported for the admin Vserver, or if a key manager for the given data Vserver is already enabled. This command is also not supported in a MetroCluster environment.

## Parameters

**-vserver <Vserver Name> - Vserver**

Use this parameter to specify the Vserver on which the AKV is to be enabled.

**-client-id <text> - Application (Client) ID of Deployed Azure Application**

Use this parameter to specify the client (application) ID of the deployed Azure application.

**-tenant-id <text> - Directory (Tenant) ID of Deployed Azure Application**

Use this parameter to specify the tenant (directory) ID of the deployed Azure application.

**-name {(ftp|http|https)://(hostname|IPv4 Address|['IPv6 Address'])...} - Deployed Azure Key Vault DNS Name**

Use this parameter to specify the DNS name of the deployed AKV.

### **[-authentication-method <AKV Authentication Method>] - Authentication Method for Azure Application**

Use this parameter to specify either `client_secret` authentication or certificate authentication for the deployed AKV.

### **-key-id {(ftp|http|https)://(hostname|IPv4 Address|['IPV6 Address'])...} - Key Identifier of AKV Key Encryption Key**

Use this parameter to specify the key identifier of the AKV Key Encryption Key (KEK).

## Examples

The following example enables the AKV for Vserver v1. An Azure application with `client-id` "4a0f9c98-c5aa-4275-abe3-2780cf2801c3", `tenant-id` "8e21f23a-10b9-46fb-9d50-720ef604be98", client secret (not echoed to the screen for security purposes) and an AKV with DNS name "https://akv-keyvault.vault.azure.net" is deployed on the Azure portal. An AKV KEK with DNS name "https://akv-keyvault.vault.azure.net/keys/key1/a8e619fd8f234db3b0b95c59540e2a74" is created on the Azure portal for the AKV.

```
cluster-1::>security key-manager external azure enable -client-id 4a0f9c98-c5aa-4275-abe3-2780cf2801c3 -tenant-id 8e21f23a-10b9-46fb-9d50-720ef604be98 -name https://akv-keyvault.vault.azure.net -key-id https://akv-keyvault.vault.azure.net/keys/key1/a8e619fd8f234db3b0b95c59540e2a74 -authentication -method client_secret -vserver v1
```

Enter the client secret for Azure Key Vault:

Re-enter the client secret for Azure Key Vault:

The following example enables the AKV for Vserver v1. An Azure application with `client-id` "4a0f9c98-c5aa-4275-abe3-2780cf2801c3", `tenant-id` "8e21f23a-10b9-46fb-9d50-720ef604be98", a client certificate (not echoed to the screen for security purposes) and an AKV with DNS name "https://akv-keyvault.vault.azure.net" is deployed on the Azure portal. An AKV KEK with DNS name "https://akv-keyvault.vault.azure.net/keys/key1/a8e619fd8f234db3b0b95c59540e2a74" is created on the Azure portal for the AKV.

```
cluster-1::>security key-manager external azure enable -client-id 4a0f9c98-c5aa-4275-abe3-2780cf2801c3 -tenant-id 8e21f23a-10b9-46fb-9d50-720ef604be98 -name https://akv-keyvault.vault.azure.net -key-id https://akv-keyvault.vault.azure.net/keys/key1/a8e619fd8f234db3b0b95c59540e2a74 -authentication -method certificate -vserver v1
```

Enter the client certificate for Azure Key Vault:

# security key-manager external azure rekey-external

Rekey an external key of the Vserver

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

This command results in the key hierarchy being protected by the user designated AKV key encryption key (KEK). Prior to running this command, the user should have already made the necessary change on the Azure portal to use a new KEK for their key vault. The key-id used in this command is the key ID associated with the user's new AKV KEK. Upon successful completion of this command, the internal keys for the given Vserver will be protected by the new AKV KEK.

## Parameters

**-vserver <Vserver Name> - Vserver**

This parameter specifies the Vserver for which ONTAP should rekey the AKV KEK.

**-key-id {(ftp|http|https)://(hostname|IPv4 Address|['IPv6 Address'])...} - Key Identifier of a new AKV Key Encryption Key**

This parameter specifies the key id of the new AKV KEK that should be used by ONTAP for the provided Vserver.

## Examples

The following command rekeys AKV KEK for data Vserver v1 using a new key-id key2.

```
cluster-1::> security key-manager external azure rekey-external -vserver v1 -key-id https://kmip-akv-keyvault.vault.azure.net/keys/key2
```

# security key-manager external azure rekey-internal

Rekey an internal key of the Vserver

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

This command rekeys the internal Vserver key hierarchy by changing the top-level internal key encryption key (KEK). Upon successful completion of the command, all keys in the Vserver key hierarchy will be protected by the new top-level KEK.

## Parameters

**-vserver <Vserver Name> - Vserver**

This parameter specifies the Vserver for which ONTAP should rekey the SVM KEK.

## Examples

The following command rekeys the SVM KEK for data Vserver v1.

```
cluster-1::> security key-manager external azure rekey-internal -vserver v1
```

# security key-manager external azure restore

Restore missing keys of Azure Key Vault

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command retrieves and restores any current unrestored keys associated with the given Vserver to the nodes internal key tables. This command is not supported when AKV has not been enabled for the Vserver.

## Parameters

**-vserver <Vserver Name> - Vserver**

This parameter specifies the Vserver to which the missing keys will be restored.

## Examples

The following command restores missing keys for the data vserver v1 (which has AKV configuration) to the internal key tables on the cluster.

```
cluster-1::> security key-manager external azure restore -vserver v1
```

# security key-manager external azure show

Display Azure Key Vaults configuration

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command displays the Azure Key Vault (AKV) configuration for a given Vserver.

## Parameters

**{ [-fields <fieldname>,...]**

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[-instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-vserver <Vserver Name>] - Vserver**

If you specify this parameter, then the command displays only the AKV configuration for the given Vserver.

**[-client-id <text>] - Application (Client) ID of Deployed Azure Application**

If you specify this parameter, then the command displays only the AKV configuration with the given client id.

**[-tenant-id <text>] - Directory (Tenant) ID of Deployed Azure Application**

If you specify this parameter, then the command displays only the AKV configuration with the given tenant id.

**[-name {(ftp|http|https)://(hostname|IPv4 Address|['IPv6 Address'])...}] - Deployed Azure Key Vault DNS Name**

If you specify this parameter, then the command displays only the AKV configuration with the given key vault name.

**[-state {available|not-responding|unknown}] - Azure Key Vault Cluster State**

If you specify this parameter, then the command displays only the AKV configuration with the given state. The state can be either available or unknown.

**[-key-id {(ftp|http|https)://(hostname|IPv4 Address|['IPv6 Address'])...}] - Key Identifier of AKV Key Encryption Key**

If you specify this parameter, then the command displays only the AKV configuration with the given key id.

**[-unavailable-nodes <text>] - Names of Unavailable Nodes**

If you specify this parameter, then the command displays only the AKV configuration with the given unavailable-nodes.

**[-authentication-method <AKV Authentication Method>] - AKV Authentication Method**

If you specify this parameter, then the command displays only the AKV configurations with the given authentication method.

## Examples

The following example lists all Vservers with AKV configuration.

```
cluster-1::>security key-manager external azure show
  Vserver: v1
  Client ID: 4a0f9c98-c5aa-4275-abe3-2780cf2801c3
  Tenant ID: 8e21f23a-10b9-46fb-9d50-720ef604be98
  Key ID: https://akv-
keyvault.vault.azure.net/keys/key1/a8e619fd8f234db3b0b95c59540e2a74
```

Name	State

# security key-manager external azure update-client-secret

(DEPRECATED)-Update client secret for Azure Key Vault

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

This command is deprecated and may be removed in a future release. Use [security key-manager external azure update-credentials](#) instead.

This command provides a way to update the client secret that is used for the Azure Key Vault (AKV) configured for the given Vserver. The command is initially set by running the [security key-manager external azure enable](#) command. This command is not supported if AKV has not been enabled for the Vserver.

## Parameters

**-vserver <Vserver Name> - Vserver**

Use this parameter to specify the Vserver for which the AKV client secret is to be updated.

## Examples

The following example updates the AKV client secret for the data Vserver v1.

```
cluster-1::> security key-manager external azure update-client-secret -vserver v1
```

```
Enter new client secret:
```

```
Re-enter new client secret:
```

# security key-manager external azure update-credentials

Update client credentials for the Azure Application

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

This command provides a way to update the authentication credentials that are used for the Azure Key Vault (AKV) configured for the given Vserver. The credentials are initially set by running the [security key-manager external azure enable](#) command. This command is not supported if AKV has not been enabled for the Vserver.

## Parameters

**-vserver <Vserver Name> - Vserver**

Use this parameter to specify the Vserver for which the AKV client credentials are to be updated.

**-authentication-method <AKV Authentication Method> - Authentication Method for the Azure Application**

Use this parameter to specify the authentication method.

## Examples

The following examples show two ways of updating the AKV client credentials for the data Vserver v1.

```
cluster-1::> security key-manager external azure update-credentials -vserver v1
-authentication-method client_secret
```

Enter new client secret:

Re-enter new client secret:

```
cluster-1:> security key-manager external azure update-credentials -vserver v1
-authentication-method certificate
```

Enter the client certificate for Azure Key Vault:

# security key-manager external gcp check

Show detailed status of the Google Cloud KMS configurations

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

This command displays the Google Cloud Key Management Service (KMS) status.

## Parameters

**{ [-fields <fieldname>,...]**

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**! [-instance ]}**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node**

If this parameter is specified then the command displays only the Google Cloud KMS status for the given node.

**[-vserver <Vserver Name>] - Vserver Name**

If this parameter is specified then the command displays only the Google Cloud KMS status for the given Vserver.

**[-category <Categories for Cloud KMS status check>] - Component**

If this parameter is specified then the command displays only the Google Cloud KMS status for the given category.

Category	Description
-----	-----
service_reachability	Cloud KMS Reachability
ekmip_server	Embedded KMIP Server Reachability
kms_wrapped_key_status	Status of KMS Wrapped Keys On Cluster

**[-status <Status Check>] - Status**

If this parameter is specified then the command displays only the Google Cloud KMS status entries matching the given status.

```
OK
FAILED
UNKNOWN
```

**[-detail <text>] - Status Details**

This field displays the detailed status message, if available.

## Examples

The example below displays the status of all components of all Google Cloud KMS configured on the node.

```
cluster-1::> security key-manager external gcp check -node vsim1
Vserver: vs1
Node: vsim1

Category: service_reachability
          Status: OK

Category: ekmip_server
          Status: OK

Category: kms_wrapped_key_status
          Status: OK
```

# security key-manager external gcp disable

Disable a Google Cloud KMS

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

This command disables the Google Cloud Key Management Service (GCKMS) associated with the given Vserver. GCKMS cannot be disabled if it is in use by ONTAP. This command will fail if GCKMS has not been enabled for the Vserver.

## Parameters

**-vserver <Vserver Name> - Vserver**

Use this parameter to specify the Vserver on which the GCKMS is to be disabled.

## Examples

The following example disables the GCKMS for Vserver v1.

```
cluster-1::>security key-manager external gcp disable -vserver v1
```

# security key-manager external gcp enable

Enable a Google Cloud KMS

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command enables the Google Cloud Key Management Service (GCKMS) associated with the given Vserver. A GCP project and GCKMS must be deployed on the GCP portal prior to running this command. GCKMS can only be enabled on a data Vserver that doesn't already have a key manager configured. GCKMS cannot be enabled in a MetroCluster environment.

## Parameters

**-vserver <Vserver Name> - Vserver**

Use this parameter to specify the Vserver on which the GCKMS is to be enabled.

**-project-id <text> - Google Cloud KMS Project(Application) ID**

Use this parameter to specify the project ID of the deployed GCP project.

**-key-ring-name <text> - Google Cloud KMS Key Ring Name**

Use this parameter to specify the key ring name of the deployed GCP project.

**-key-ring-location <text> - Google Cloud KMS Key Ring Location**

Use this parameter to specify the location of the key ring.

**-key-name <text> - Google Cloud KMS Key Encryption Key Name**

Use this parameter to specify the key name of the GCKMS Key Encryption Key (KEK).

## Examples

The following example enables the GCKMS for Vserver v1. The parameters in the example command identify a Google Cloud Platform (GCP) project application deployed on the GCP. The GCP project application has a Project ID "test\_project", a key ring name "key\_ring\_for\_test\_project", a key ring location "secure\_location\_for\_key\_ring" and a key name "testKEK".

```
cluster-1::*> security key-manager external gcp enable -vserver v1 -project-id
test_project -key-ring-name key_ring_for_test_project -key-ring-location
secure_location_for_key_ring -key-name testKEK
```

Enter the contents of the Google Cloud Key Management Service account key file (json file): Press <Enter> when done

# security key-manager external gcp rekey-external

Rekey an external key of the Vserver

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command replaces the existing GCP key encryption key (KEK) and results in the key hierarchy being protected by the user specified GCP KEK. The GCP key ring in use by the GCP Portal should be updated to use the new KEK prior to running this command. Upon successful completion of this command, the internal keys for the given Vserver will be protected by the new GCP KEK.

## Parameters

**-vserver <Vserver Name> - Vserver**

This parameter specifies the Vserver for which ONTAP should rekey the GCP KEK.

**-key-name <text> - Google Cloud KMS Key Encryption Key Name**

This parameter specifies the key name of the new GCP KEK that should be used by ONTAP for the provided Vserver.

**[-project-id <text>] - Google Cloud KMS Project (Application) ID**

This parameter specifies the new project ID of the new GCP KEK that should be used by ONTAP for the provided Vserver.

**[-key-ring-name <text>] - Google Cloud KMS Key Ring Name**

This parameter specifies the new key ring name of the new GCP KEK that should be used by ONTAP for the provided Vserver.

**[-key-ring-location <text>] - Google Cloud KMS Key Ring Location**

This parameter specifies the new key ring location of the new GCP KEK that should be used by ONTAP for the provided Vserver.

## Examples

The following command rekeys GCP KEK for data Vserver v1 using a new key-name key1.

```
cluster-1::> security key-manager external gcp rekey-external -vserver v1 -key-name key1
```

# security key-manager external gcp rekey-internal

Rekey an internal key of the Vserver

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

This command rekeys the internal Vserver key hierarchy by changing the SVM key encryption key (KEK). Upon successful completion of the command, all keys in the Vserver key hierarchy will be protected by the new top-level KEK.

## Parameters

**-vserver <Vserver Name> - Vserver**

This parameter specifies the Vserver for which ONTAP should rekey the SVM KEK.

## Examples

The following command rekeys the SVM KEK for data Vserver v1.

```
cluster-1::> security key-manager external gcp rekey-internal -vserver v1
```

# security key-manager external gcp restore

Restore missing keys of a Google Cloud KMS

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command retrieves and restores any unrestored keys associated with the given Vserver to each node's internal key tables.

## Parameters

**-vserver <Vserver Name> - Vserver**

This parameter specifies the Vserver to which the missing keys will be restored.

## Examples

The following command restores missing keys for the data Vserver v1 (which has GCKMS enabled) to the internal key tables on each node in the cluster.

```
cluster-1::> security key-manager external gcp restore -vserver v1
```

# security key-manager external gcp show

Display Google Cloud KMS configuration

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command displays the Google Cloud Key Management Service (GCKMS) configuration.

## Parameters

**{ [-fields <fieldname>,...]**

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[-instance ]}**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-vserver <Vserver Name>] - Vserver**

If you specify this parameter, then the command displays only the GCKMS configuration for the given Vserver.

**[-project-id <text>] - Google Cloud KMS Project (Application) ID**

If you specify this parameter, then the command displays only the GCKMS configuration with the given project id.

**[-key-ring-name <text>] - Google Cloud KMS Key Ring Name**

If you specify this parameter, then the command displays only the GCKMS configuration with the given key ring name.

**[-key-ring-location <text>] - Google Cloud KMS Key Ring Location**

If you specify this parameter, then the command displays only the GCKMS configuration with the given key ring location.

**[-key-name <text>] - Google Cloud KMS Key Encryption Key Name**

If you specify this parameter, then the command displays only the GCKMS configuration with the given key name.

**[-state {available|not-responding|unknown}] - Google Cloud KMS Cluster State**

If you specify this parameter, then the command displays only the GCKMS configuration with the given state. The state can be either available or unknown.

**[-unavailable-nodes <text>] - Names of Unavailable Nodes**

If you specify this parameter, then the command displays only the GCKMS configuration with the given unavailable-nodes.

## Examples

The following example lists all Vservers with GCKMS configuration.

```
cluster-1::>security key-manager external gcp show
      Vserver: SAMPLE_VSERVER
      Project ID: SAMPLE_PROJECT_ID
      Key Ring Location: SAMPLE_KEY_RING_LOCATION
      Key Name: SAMPLE_KEY_NAME
```

Key Ring Name	State
-----	-----
SAMPLE_KEY_RING_NAME	unknown
Unavailable Nodes:	node1

# security key-manager external gcp update-credentials

## Update Google Cloud Project's Service Account Credentials

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

This command allows the user to update the application credential which is used by the Google Cloud Key Management Service (GCKMS) configured for the given Vserver. The application credential is initially set by running the [security key-manager external gcp enable](#) command. This command will fail if GCKMS has not been enabled for the Vserver.

## Parameters

**-vserver <Vserver Name> - Vserver**

Use this parameter to specify the Vserver for which the GCKMS application credential will be updated.

## Examples

The following example updates the GCKMS application credential for the data Vserver v1.

```
cluster-1::> security key-manager external gcp update-credentials -vserver v1

Enter the new application credential: Press <Enter> when done
```

# security key-manager key create

Create a new authentication key

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command creates a new authentication key (AK) and stores it on the the admin Vserver's key management servers. The command fails if the configured key management servers are already storing more than 256 AKs. If this command fails because there are more than 256 AKs in the cluster, delete unused keys on the Vserver's key management servers and retry the command. This command is not supported when external key management is not enabled for the admin Vserver.

## Parameters

### **[-key-tag <text>] - Key Tag**

This parameter specifies the key tag to associate with the new authentication key (AK). The default value is the node name. This parameter can be used to help identify created authentication keys (AKs). For example, the [security key-manager key query](#) command's key-tag parameter can be used to query for a specific key-tag value.

### **[-prompt-for-key {true|false}] - Prompt for Authentication Passphrase**

If you specify this parameter as true, then the command prompts you to enter an authentication passphrase manually instead of generating it automatically. For security reasons, the authentication passphrase you entered is not displayed at the command prompt. You must enter the authentication passphrase a second time for verification. To avoid errors, copy and paste authentication passphrases electronically instead of entering them manually. Data ONTAP saves the resulting authentication key/key ID pair automatically on the configured key management servers.

## Examples

The following example creates an authentication key with the node name as the default key-tag value:

```
cluster-1::> security key-manager key create
Key ID:
00000000000000000000200000000000100d0f7c2462d626b739fe81b89f29a092f0000000000000000
```

The following example creates an authentication key with a user-specified authentication passphrase:

```
cluster-1::> security key-manager key create -prompt-for-key true
Enter a new passphrase:
Reenter the passphrase:
Key ID:
000000000000000000002000000000001006268333f870860128fbe17d393e5083b000000000000000
```

## Related Links

- [security key-manager key query](#)

# security key-manager key delete

Delete an existing authentication key

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command removes an authentication key from the configured key management servers on the admin Vserver. The command fails if the given key is currently in use by Data ONTAP. This command is not supported when external key management is not enabled for the admin Vserver.

## Parameters

**-key-id <Hex String> - Authentication Key ID**

Use this parameter to specify the key ID of the key that you want to remove.

## Examples

The following example deletes an authentication key:

```
cluster-1::*> security key-manager key delete -key-id
000000000000000000002000000000001006268333f870860128fbe17d393e5083b000000000000000
```

# security key-manager key migrate

Migrate keys from the admin Vserver's the Onboard Key Manager to a data Vserver's external key manager and vice versa

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *advanced* privilege level.

## Description

This command provides a mechanism to migrate the existing keys of a data Vserver from the admin Vserver's key manager to their own key manager or vice versa. The keys stay the same and the data is not rekeyed, only the keys are migrated from one Vserver's key manager to another. After a successful migration to the new key manager, the data Vserver keys are deleted from the previous key manager.

## Parameters

### **-from-vserver <vserver name> - Vserver Name**

Use this parameter to specify the name of the Vserver whose key manager the keys are migrated from.

### **-to-vserver <vserver name> - Vserver Name**

Use this parameter to specify the name of the Vserver whose key manager the keys are migrated to.

## Examples

The following example migrates the keys of "datavs" data Vserver from "cluster-1" admin Vserver's key manager to "datavs" data Vserver's key manager:

```
cluster-1::> security key-manager key migrate -from-vserver cluster-1 -to-vserver
datavs
```

The following example migrates the keys of "datavs" data Vserver from "datavs" data Vserver's key manager to "cluster-1" admin Vserver's key manager:

```
cluster-1::> security key-manager key migrate -from-vserver datavs -to-vserver
cluster-1
```

## security key-manager key query

Display the key IDs.

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command displays the IDs of the keys that are stored in the configured key managers. This command does not update the key tables on the node. Primary key servers, along with any associated secondary key servers, are displayed in the output.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[ -node {<nodename>|local} ] - Node**

Use this parameter to specify the name of the node that queries the specified key management servers. If this parameter is not specified, then all nodes query the specified key management servers.

**[ -vserver <vserver name> ] - Vserver Name**

Use this parameter to specify the Vserver for which to list the keys.

**[ -key-server <Hostname and Port> ] - Key Server**

This parameter specifies the host and port of the key management server that you want to query. This parameter is used only with external key managers.

**[ -key-id <Hex String> ] - Key Identifier**

If you specify this parameter, then the command displays only the key IDs that match the specified value.

**[ -key-tag <text> ] - Key Tag**

If you specify this parameter, then the command displays only the key IDs that match the specified value. The key-tag for Volume Encryption Keys (VEKs) is set to the UUID of the encrypted volume.

**[ -key-type <Key Usage Type> ] - Key Type**

If you specify this parameter, then the command displays only the key IDs that match the specified value.

**[ -restored {true|false} ] - Restored**

This parameter specifies whether the key corresponding to the displayed key ID is present in the specified node's internal key table. If you specify **'true'** for this parameter, then the command displays the key IDs of only those keys that are present in the system's internal key table. If you specify **'false'** for this parameter, then the command displays the key IDs of only those keys that are not present in the system's internal key table.

**[-key-store <Key Store>] - Key Store**

Use this parameter to specify the key manager type from which to list the keys.

**[-key-user <vserver name>] - Key User**

If you specify this parameter, then the command displays only the key IDs that are used by the specified Vserver.

**[-key-manager <text>] - Key Manager**

This parameter specifies the identity of the key manager. For external key managers that will be the host and the port of the key server. In other cases that will be the name of a corresponding key manager.

**[-key-store-type <Key Store Type>] - Key Store Type**

If you specify this parameter, then the command displays only the key IDs that are used by the specified key manager type.

**[-crn <text>] - Cloud Resource Name**

This parameter specifies the Cloud Resource Name (CRN) of the key. If you specify this parameter, then the command displays only the key IDs that contains such CRN.

**[-policy <text>] - Key Store Policy**

This optional parameter specifies the policy name of the key manager. If you specify this parameter, then the command displays only the key IDs that are associated with the specified policy.

**[-encryption-algorithm <text>] - Encryption algorithm for the key**

This optional parameter specifies the encryption algorithm of the key. If you specify this parameter, then the command displays only the keys of the specified algorithm type.

## Examples

The following example shows all of the keys on all configured key servers, and whether or not those keys have been restored for all nodes in the cluster:

```
cluster-1::> security key-manager key query
Node: node1
      Vserver: cluster-1
      Key Manager: onboard
      Key Manager Type: OKM

## security key-manager key show

(DEPRECATED)-Display encryption key IDs stored in the Onboard Key Manager

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

This command is deprecated and might be removed in a future release. Use [security key-manager key query](#) instead.

This command displays the key IDs of the authentication keys (NSE-AK) and SVM keys (SVM-KEK) that are available in Onboard Key Manager. This command is not supported for an external key management configuration.

### Parameters

**{ [-fields <fieldname>, ... ]**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[ [-detail ]**

If this parameter is specified, the command displays additional details about the key IDs.

**[ [-instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node**

If this parameter is specified, the command displays information only about key IDs that are located on the specified storage system.

**[-key-store <Key Store>] - Key Store**

If this parameter is specified, the command displays information only about key IDs that are managed by the specified key management. For example, use **onboard** for the Onboard Key Manager.

**[-key-id <text>] - Key Identifier**

If this parameter is specified, the command displays information only about the specified key IDs.

**[-key-tag <text>] - Key Tag**

If this parameter is specified, the command displays information only about key IDs that have the specified key tags.

**[-key-location <text>] - Key Location**

If this parameter is specified, the command displays information only about key IDs that are located on the specified key location. For example, use **local-cluster** for the Onboard Key Manager.

**[-used-by <Key Usage Type>] - Used By**

If this parameter is specified, the command displays information only about key IDs that are associated with the specified application usage of the keys. For example, "NSE-AK" would display key IDs only for NSE drives.

**[-restored {yes|no}] - Restored**

If this parameter is specified, the command displays information only about key IDs that have the specified value of restored keys. If restored is **yes**, then the corresponding key is available (normal). If restored is **no**, use the [security key-manager setup](#) command to restore the key. See the man page for [security key-manager setup](#) for details.

## Examples

The following example shows all keys stored in the Onboard Key Manager:

```
cluster-1::> security key-manager key show

# security key-manager key key-table create

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command creates an entry in the key manager key table. It does not create a new key.

## Parameters

### **-key-id <Hex String> - Key ID**

This parameter specifies the key ID of the new entry in the table.

### **-key-type <Key Usage Type> - Key Usage Type**

This parameter specifies the key type of the new entry. The following key types are supported: NSE-AK, AEK, VEK, NEK and SVM-KEK.

### **-encryption-algorithm <text> - Encryption Algorithm For The Key**

This parameter specifies the encryption algorithm associated with the key.

### **-creation-time <MM/DD/YYYY HH:MM:SS> - Key Creation Time**

This parameter specifies the date and time that the key was created. The date and time format is "MM/DD/YYYY HH:MM:SS".

## Examples

The following example creates an entry in the table:

```
cluster-1::> security key-manager key key-table create -key-id
00000000000000000000200000000000500e9ccf3f08e7533d9cd0298e1ebe6c10000000000000000 -key
-type SVM-KEK -encryption-algorithm AES-256 -creation-time 01/01/2022 01:01:59

cluster-1::> security key-manager key key-table show

Key ID                                                                                               Key
Type Encryption   Creation Time
-----
00000000000000000000200000000000500e9ccf3f08e7533d9cd0298e1ebe6c10000000000000000 SVM-
KEK AES-256      1/1/2022 01:01:59
1 entry was displayed.
```

# security key-manager key key-table delete

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command removes an entry from the key table.

## Parameters

**-key-id <Hex String>** - Key ID

Use this parameter to specify the key ID of the entry that you want to remove from the key table.

## Examples

The following example deletes an entry from the key table:

```
cluster-1::> security key-manager key key-table show
```

Key ID	Key
Type Encryption    Creation Time	
-----	-----
00000000000000000000200000000000100239c17902e7515ed397892f75f52e38e0000000000000000	NSE-
AK    AES-256            2/8/2022 10:54:46

1 entry was displayed.

# security key-manager key key-table modify

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command modifies an entry in the key table. Changes made using this command do not affect the key; only the table entry is modified, not the key itself.

## Parameters

**-key-id <Hex String> - Key ID**

This parameter specifies the key ID of the entry to be modified.

**[-key-type <Key Usage Type>] - Key Usage Type**

If this optional parameter is specified, the key type field is modified accordingly.

**[-encryption-algorithm <text>] - Encryption Algorithm For The Key**

If this optional parameter is specified, the encryption algorithm field is modified accordingly.

**[-creation-time <MM/DD/YYYY HH:MM:SS>] - Key Creation Time**

If this optional parameter is specified, the creation time field is modified accordingly.

## Examples

The following example shows the key table before and after the modify command:

```
cluster-1::> security key-manager key key-table show
```

Key ID	Key
Type Encryption Creation Time	
00000000000000000000200000000000500e9ccf3f08e7533d9cd0298e1ebe6c11900000000000000000	VEK

## security key-manager key key-table show

Display details of a specific key ID.

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

This command displays date and time information for all keys.

### Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-key-id <Hex String>] - Key ID**

If this parameter is specified, the command displays the key that has the specified key ID.

**[-key-type <Key Usage Type>] - Key Usage Type**

If this parameter is specified, the command only displays information about keys with the specified key type.

**[-encryption-algorithm <text>] - Encryption Algorithm For The Key**

If this parameter is specified, the command only displays information about keys with the specified encryption algorithm.

**[-creation-time <MM/DD/YYYY HH:MM:SS>] - Key Creation Time**

If this parameter is specified, the command displays only information about keys with the specified creation time.

### Examples

The following example shows all date and time information for all keys:

```
cluster-1::> security key-manager key key-table show
```

Key ID	Type	Encryption	Creation Time	Key
000000000000000000002000000000001000f3ee496cd5820cfb76dd2ce3fa7661b000000000000000	AK	AES-256	1/30/2022 04:21:40	NSE-

4 entries were displayed.

## security key-manager onboard disable

Disable the Onboard Key Manager

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

This command disables the Onboard Key Manager associated with the admin Vserver and permanently deletes the Onboard Key Manager configuration associated with the admin Vserver. The Onboard Key Manager cannot be disabled if there are any encrypted volumes that use encryption keys created by the Onboard Key Manager. This command fails if the Onboard Key Manager is not enabled.

### Examples

The following example disables the Onboard Key Manager for the admin Vserver:

```
cluster-1::*> security key-manager onboard disable
```

```
Warning: This command will permanently delete all keys from Onboard Key
Manager.
```

```
Do you want to continue? {y|n}: y
```

## security key-manager onboard enable

Enable the Onboard Key Manager

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command enables the Onboard Key Manager for the admin Vserver.

## Parameters

### `[-cc-mode-enabled {yes|no}] - Enable Common Criteria Mode?`

Use this parameter to specify whether the Common Criteria (CC) mode should be enabled or not. When CC mode is enabled, you are required to provide a cluster passphrase that is between 64 and 256 ASCII character long, and you are required to enter that passphrase each time a node reboots. CC mode cannot be enabled in a MetroCluster configuration.

### `[-are-unencrypted-metadata-volumes-allowed-in-cc-mode {yes|no}] - Are Unencrypted Metadata Volumes Allowed in Common Criteria Mode`

If Common Criteria (CC) mode is enabled this parameter allows unencrypted metadata volumes to exist. These metadata volumes are created internally during normal operation. Examples are volumes created during SnapMirror and Vserver migrate operations. the default value is **no**.

## Examples

The following example enables the Onboard Key Manager for the admin Vserver cluster-1:

```
cluster-1::> security key-manager onboard enable
```

Enter the cluster-wide passphrase for the Onboard Key Manager:

Re-enter the cluster-wide passphrase:

After configuring the Onboard Key Manager, save the encrypted configuration data in a safe location so that you can use it if you need to perform a manual recovery operation. To view the data, use the "security key-manager onboard show-backup" command.

## security key-manager onboard show-backup

Display the Onboard Key Management backup

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command displays the backup information for the Onboard Key Manager for the admin Vserver, which can be used to recover the cluster in case of catastrophic situations. The information displayed is for the cluster as a whole (not individual nodes).

# security key-manager onboard sync

Sync the Onboard Key Manager keys

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command synchronizes missing onboard keys on any node in the cluster. For example, if you add a node to a cluster that has the Onboard Key Manager configured, you should then run this command to synchronize the keys. In a MetroCluster configuration, if the [security key-manager onboard enable](#) command is used to enable the Onboard Key Manager on one site, then run the **security key-manager onboard sync** command on the partner site. In a MetroCluster configuration, if the [security key-manager onboard update-passphrase](#) command is used to update the passphrase on one site, then run this command with the new passphrase on the partner site before proceeding with any key management operations.

## Parameters

## Examples

The following example synchronizes the Onboard Key Manager key database across all nodes in the cluster. In a MetroCluster configuration, this command synchronizes nodes in the local site.

```
cluster-1::> security key-manager onboard sync
```

## Related Links

- [security key-manager onboard enable](#)
- [security key-manager onboard update-passphrase](#)

# security key-manager onboard update-passphrase

Update the Onboard Key Manager Passphrase

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command provides a way to update the cluster-wide passphrase that is used for the Onboard Key Manager and initially created by running the [security key-manager onboard enable](#) command.

This command prompts for the existing passphrase, and if that passphrase is correct then the command prompts for a new passphrase. When the Onboard Key Manager is enabled for the admin Vserver, run the [security key-manager onboard show-backup](#) command after updating the passphrase and save the output for emergency recovery scenarios. When the **security key-manager onboard update-passphrase** command is executed in a MetroCluster configuration, then run the [security key-manager onboard sync](#) command with the new passphrase on the partner site before proceeding with any key-manager operations. This allows the updated passphrase to be replicated to the partner site.

## Examples

The following example updates the cluster-wide passphrase used for the Onboard Key Manager:

```
cluster-1::*> security key-manager onboard update-passphrase
```

```
Warning: This command will reconfigure the cluster passphrase for onboard  
key management.
```

```
Do you want to continue? {y|n}: y
```

```
Enter current passphrase:
```

```
Enter new passphrase:
```

```
Reenter the new passphrase:
```

```
Update passphrase has completed. Save the new encrypted configuration data in  
a safe location so that you can use it if you need to perform a manual recovery  
operation. To view the data, use the "security key-manager onboard show-backup"  
command.
```

# security key-manager onboard verify-backup

Verify the onboard key management backup and its passphrase

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command verifies the backup data and the passphrase of the Onboard Key Manager for the

# security key-manager policy show

Display key manager policy

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command displays the defined key management key policies.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[ -policy <text> ] - Policy name**

If you specify this parameter, then the command will list the key manager policy with the given name.

**[ -check-key-on-online {true|false} ] - Pull key from key manager during volume online?**

If you specify this parameter, then the command displays only the key manager policies with the given check-key-on-online value.

**[ -purge-key-on-offline {true|false} ] - Purge key from memory during volume offline?**

If you specify this parameter, then the command displays only the key manager policies with the given purge-key-on-offline value.

**[ -support-on-admin-vserver {true|false} ] - Support policy on admin Vserver?**

If you specify this parameter, then the command displays only the key manager policies with the given support-on-admin-vserver value.

**[ -key-manager-attribute-required {true|false} ] - Key manager attribute required for volume?**

If you specify this parameter, then the command displays only the key manager policies with the given key-manager-attribute-required value.

## Examples

The following example lists all configured key management policies:

```
cluster-1::*> security key-manager policy show
```

Policy	Check Key on Online?	Purge Key on Offline?
IBM_Key_Lore	true	true

## security login create

Add a login method

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **security login create** command creates a login method for the management utility. A login method consists of a user name, an application (access method), and an authentication method. A user name can be associated with multiple applications. It can optionally include an access-control role name. If an Active Directory, LDAP, or NIS group name is used, then the login method gives access to users belonging to the specified group. If the user is a member of multiple groups provisioned in the security login table, then the user will get access to a combined list of the commands authorized for the individual groups.

### Parameters

**-vserver <vserver name> - Vserver**

This specifies the Vserver name of the login method.

**-user-or-group-name <text> - User Name or Group Name**

This specifies the user name or Active Directory, LDAP, or NIS group name of the login method. The Active Directory, LDAP, or NIS group name can be specified only with the **domain** or **nsswitch** authentication method and **ontapi** and **ssh** application. If the user is a member of multiple groups provisioned in the security login table, then the user will get access to a combined list of the commands authorized for the individual groups.

**-application <text> - Application**

This specifies the application of the login method. Possible values include **amqp**, **console**, **http**, **ontapi**, **rsh**, **snmp**, **service-processor**, **ssh**, and **telnet**.

Setting this parameter to **service-processor** grants the user access to the Service Processor (SP). Because the SP supports only password authentication, when you set this parameter to **service-processor**, you must also set the **-authentication-method** parameter to **password**. Vserver user accounts cannot access the SP. Therefore, you cannot use the **-vserver** parameter when you set this parameter to **service-processor**.

**-authentication-method <text> - Authentication Method**

This specifies the authentication method for login. Possible values include the following:

- cert - SSL certificate authentication
- community - SNMP community strings
- domain - Active Directory authentication
- nsswitch - LDAP or NIS authentication
- password - Password
- publickey - Public-key authentication
- usm - SNMP user security model
- saml - SAML authentication

#### **[-remote-switch-ipaddress <IP Address>] - Remote Switch IP Address**

This specifies the IP address of the remote switch. The remote switch could be a cluster switch monitored by cluster switch health monitor (CSHM) or a Fibre Channel (FC) switch monitored by MetroCluster health monitor (MCC-HM). This parameter is applicable only when the application is **snmp** and authentication method is **usm** (SNMP user security model).

#### **-role <text> - Role Name**

This specifies an access-control role name for the login method.

#### **[-comment <text>] - Comment Text**

This specifies comment text for the user account, for example, "Guest account". The maximum length is 128 characters.

#### **[-is-ns-switch-group {yes|no}] - Whether Ns-switch Group**

This specifies whether **user-or-group-name** is an LDAP or NIS group. Possible values are yes or no. Default value is no.

#### **[-second-authentication-method {none|publickey|password|nsswitch}] - Second Authentication Method2**

This specifies the authentication method for the login. It will be used as the second factor for authentication. Possible values include the following:

- password - Password
- publickey - Public-key authentication
- nsswitch - NIS or LDAP authentication
- none - default value

#### **[-is-ldap-fastbind {yes|no}] - LDAP Fastbind Authentication**

This flag specifies whether the authentication is LDAP fastbind or Not. Default:false

## Examples

The following example illustrates how to create a login that has the user name **monitor** , the application **ssh** , the authentication method **password** , and the access-control role **guest** for Vserver **vs** :

```
cluster1::> security login create -vserver vs -user-or-group-name monitor
-application ssh -authentication-method password -role guest
```

The following example illustrates how to create a login that has the user name **monitor** , the application **ontapi** , the authentication method **password** , and the access-control role **vsadmin** for Vserver **vs** :

```
cluster1::> security login create -vserver vs -user-or-group-name monitor
-application ontapi -authentication-method password -role vsadmin
```

The following example illustrates how to create a login that has the user name **monitor** , the application **ssh** , the authentication method **publickey** , and the access-control role **guest** for Vserver **vs** :

```
cluster1::> security login create -vserver vs -user-or-group-name monitor
-application ssh -authentication-method publickey -role guest
```

The following example illustrates how to create a login that has the user name **monitor** , the application **http** , the authentication method **cert** , and the access-control role **admin** for Vserver **vs** :

```
cluster1::> security login create -vserver vs -user-or-group-name monitor
-application http -authentication-method cert -role admin
```

The following example illustrates how to create a login that has the Active Directory group name **adgroup** in **DOMAIN1** , the application **ssh** , the authentication method **domain** , and the access-control role **vsadmin** for Vserver **vs** :

```
cluster1::> security login create -vserver vs
-user-or-group-name DOMAIN1\adgroup -application ssh
-authentication-method domain -role vsadmin
```

The following example illustrates how to create a login that has a group name **nssgroup** in the LDAP or NIS server, the application **ontapi** , the authentication method **nsswitch** , and the access-control role **vsadmin** for Vserver **vs** . Here **is-ns-switch-group** must be set to **yes** :

```
cluster1::> security login create -vserver vs -user-or-group-name nssgroup
-application ontapi -authentication-method nsswitch -role vsadmin
-is-ns-switch-group yes
```

The following example illustrates how to create a login that has the user name **monitor** , the application **ssh** , the authentication method **password** , the second authentication method **publickey** and the access-control role **vsadmin** for Vserver **vs** :

```
cluster1::> security login create -vserver vs -user-or-group-name monitor
  -application ssh -authentication-method password
  -second-authentication-method publickey -role vsadmin
```

The following example illustrates how to create a login that has the user name **monitor** , the application **ssh** , the authentication method **password** , the second authentication method **none** and the access-control role **vsadmin** for Vserver **vs** :

```
cluster1::> security login create -vserver vs -user-or-group-name monitor
  -application ssh -authentication-method password
  -second-authentication-method none -role vsadmin
```

## security login delete

Delete a login method

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **security login delete** command deletes a login method.

### Parameters

**-vserver <vserver name> - Vserver**

This optionally specifies the Vserver name of the login method.

**-user-or-group-name <text> - User Name or Group Name**

This specifies the user name or Active Directory, LDAP, or NIS group name of the login method that is to be deleted. A user name can be associated with multiple applications.

**-application <text> - Application**

This specifies the application of the login method. Possible values include amqp, console, http, ontapi, rsh, snmp, service-processor, ssh, and telnet.

**-authentication-method <text> - Authentication Method**

This specifies the authentication method of the login method. Possible values include the following:

- cert - SSL certificate authentication
- community - SNMP community strings
- domain - Active Directory authentication
- nsswitch - LDAP or NIS authentication

- password - Password
- publickey - Public-key authentication
- usm - SNMP user security model
- saml - SAML authentication

### **[-remote-switch-ipaddress <IP Address>] - Remote Switch IP Address**

This specifies the IP address of the remote switch. The remote switch could be a cluster switch monitored by cluster switch health monitor (CSHM) or a Fibre Channel (FC) switch monitored by MetroCluster health monitor (MCC-HM). This parameter is applicable only when the application is **snmp** and authentication method is **usm** (SNMP user security model).

## Examples

The following example illustrates how to delete a login that has the username **guest**, the application **ssh**, and the authentication method **password** for Vserver **vs**:

```
cluster1::> security login delete -user-or-group-name guest
-application ssh -authentication-method password -vserver vs
```

The following example illustrates how to delete a login that has the username **guest**, the application **ontapi**, and the authentication method **cert** for Vserver **vs**:

```
cluster1::> security login delete -user-or-group-name guest
-application ontapi -authentication-method cert -vserver vs
```

The following example illustrates how to delete a login that has the Active Directory group name **adgroup** in **DOMAIN1**, the application **ssh**, and the authentication method **domain** for Vserver **vs**:

```
cluster1::> security login delete -user-or-group-name DOMAIN1\adgroup
-application ssh -authentication-method domain -vserver vs
```

The following example illustrates how to delete a login that has a group name **nssgroup** in the LDAP or NIS server, the application **ontapi**, and the authentication method **nsswitch** for Vserver **vs**:

```
cluster1::> security login delete -user-or-group-name nssgroup
-application ontapi -authentication-method nsswitch -vserver vs
```

## security login expire-password

Expire user's password

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **security login expire-password** command expires a specified user account password, forcing the user to change the password upon next login.

## Parameters

**-vserver <vserver name> - Vserver**

This optionally specifies the Vserver to which the user account belongs.

**-username <text> - Username**

This specifies the user name of the account whose password you want to expire.

**[-hash-function {sha512|sha256}] - Password Hash Function**

This optionally specifies the password-hashing algorithm used for encrypting the passwords that you want to expire. The supported values include are as follows:

- sha512 - Secure hash algorithm (512 bits)
- sha256 - Secure hash algorithm (256 bits)
- md5 - Message digest algorithm (128 bits)

**[-lock-after <integer>] - Lock User Account After N days**

This optionally specifies the number of days after which the new password hash policy will be enforced. The enforcement will lock all user accounts that are still compliant with the provided hash algorithm using **-hash-function** parameter.

## Examples

The following command expires the password of the 'jdoe' user account which belongs to the 'vs1' Vserver.

```
cluster1::> security login expire-password -vserver vs1 -username jdoe
```

The following command expires all user account passwords that are encrypted with the MD5 hash function.

```
cluster1::> security login expire-password -vserver * -username * -hash-function md5
```

The following command expires the password of any Vserver's user account named 'jdoe' that is encrypted with the MD5 hash function.

```
cluster1::> security login expire-password -vserver * -username jdoe -hash-function md5
```

The following command expires the password of the 'vs1' Vserver user account named 'jdoe' that is encrypted with the MD5 hash function.

```
cluster1::> security login expire-password -vserver vs1 -username jdoe -hash-function md5
```

The following command expires all user account passwords that are encrypted with the MD5 hash function and enforce the new password hash policy after 180 days.

```
cluster1::> security login expire-password -vserver * -username * -hash-function md5 -lock-after 180
```

## security login lock

Lock a user account with password authentication method

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **security login lock** command locks a specified account, preventing it from accessing the management interface.

### Parameters

**-vserver <vserver name> - Vserver**

This optionally specifies the Vserver to which the user account belongs.

**-username <text> - Username**

This specifies the user name of the account that is to be locked.

### Examples

The following example locks a user account named 'jdoe' which belongs to the Vserver 'vs1'.

```
cluster1::> security login lock -vserver vs1 -username jdoe
```

## security login modify

Modify a login method

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **security login modify** command modifies the access-control role name of a login method. If the user is a member of multiple groups provisioned in the security login table, then the user will get access to a combined list of the commands authorized for the individual groups.

## Parameters

### **-vserver <vserver name> - Vserver**

This specifies the Vserver name of the login method.

### **-user-or-group-name <text> - User Name or Group Name**

This specifies the user name, Active Directory, LDAP, or NIS group name of the login method that is to be modified. A user name can be associated with multiple applications. If the user is a member of multiple groups provisioned in the security login table, then the user will get access to a combined list of the commands authorized for the individual groups.

### **-application <text> - Application**

This specifies the application of the login method. Possible values include amqp, console, http, ontapi, rsh, snmp, service-processor, ssh, and telnet.

### **-authentication-method <text> - Authentication Method**

This specifies the authentication method of the login method. Possible values include the following:

- cert - SSL certificate authentication
- community - SNMP community strings
- domain - Active Directory authentication
- nsswitch - LDAP or NIS authentication
- password - Password
- publickey - Public-key authentication
- usm - SNMP user security model
- saml - SAML authentication

### **[-remote-switch-ipaddress <IP Address>] - Remote Switch IP Address**

This specifies the IP address of the remote switch. The remote switch could be a cluster switch monitored by cluster switch health monitor (CSHM) or a Fibre Channel (FC) switch monitored by MetroCluster health monitor (MCC-HM). This parameter is applicable only when the application is **snmp** and authentication method is **usm** (SNMP user security model).

### **[-role <text>] - Role Name**

This modifies the access-control role name for the login method.

### **[-comment <text>] - Comment Text**

This specifies comment text for the user account, for example, "Guest account". The maximum

length is 128 characters.

### **[-is-ns-switch-group {yes|no}] - Whether Ns-switch Group**

This specifies if **user-or-group-name** is an LDAP or NIS group. Possible values are yes or no. Default value is no.

### **[-second-authentication-method {none|publickey|password|nsswitch}] - Second Authentication Method2**

This specifies the authentication method for the login method. It will be used as the second factor for authentication. Possible values include the following:

- password - Password
- publickey - Public-key authentication
- nsswitch - NIS or LDAP authentication
- none - default value

### **[-is-ldap-fastbind {yes|no}] - LDAP Fastbind Authentication**

This flag specifies whether modify is allowed or not when the authentication is LDAP fastbind.

## Examples

The following example illustrates how to modify a login method that has the user name **guest**, the application **ontapi**, and the authentication method **password** to use the access-control role **guest** for Vserver **vs**:

```
cluster1::> security login modify -user-or-group-name guest
  -application ontapi -authentication-method password -role guest
  -vserver vs
```

The following example illustrates how to modify a login method that has the user name **guest**, the application **ssh**, and the authentication method **publickey** to use the access-control role **vsadmin** for Vserver **vs**:

```
cluster1::> security login modify -user-or-group-name guest
  -application ssh -authentication-method publickey -role vsadmin
  -vserver vs
```

The following example illustrates how to modify a login method that has the group name **nssgroup**, the application **ontapi**, and the authentication method **nsswitch** to use the access-control role **readonly** for Vserver **vs**. Here **is-ns-switch-group** must be set to **yes**:

```
cluster1::> security login modify -user-or-group-name nssgroup
  -application ontapi -authentication-method nsswitch -role readonly
  -vserver vs -is-ns-switch-group yes
```

The following example illustrates how to modify a login method that has the user name **guest** , the application **ssh** , and the authentication method **publickey** to use the second-authentication-method **password** for Vserver **vs** :

```
cluster1::> security login modify -user-or-group-name guest
  -application ssh -authentication-method publickey
  -second-authentication-method password -vserver vs
```

The following example illustrates how to modify a login method to have individual authentication methods that have the user name **guest** , the application **ssh** , and the authentication method **publickey** to use the second-authentication-method **none** for Vserver **vs** :

```
cluster1::> security login modify -user-or-group-name guest
  -application ssh -authentication-method publickey
  -second-authentication-method none -vserver vs
```

## security login password-prepare-to-downgrade

Reset password features introduced in the Data ONTAP version

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

If the password of the system administrator is not encrypted with an encryption type supported by releases earlier than ONTAP 9.0, this command prompts the administrator for a new password and encrypt it using a supported encryption type on each cluster or at each site in a MetroCluster configuration. In a MetroCluster configuration, this command must be run on both sites. The password for all other users are marked as "expired". This causes them to be re-encrypted using a compatible encryption type. The expired passwords are changed with an internally generated password. The administrator must change the passwords for all users before the users can login. The users are prompted to change their password upon login. This command disables the logging of unsuccessful login attempts. The command must be run by a user with the cluster admin role from a clustershell session on the console device. This user must be unlocked. If you fail to run this command, the revert process fails.

### Parameters

**-disable-feature-set <downgrade version> - Data ONTAP Version**

This parameter specifies the Data ONTAP version that introduced the password feature set.

## Examples

The following command disables the logging of unsuccessful login attempts.

```
cluster1::*> security login password prepare-to-downgrade -disable-feature-set 8.3.1

Warning: This command will disable the MOTD feature that prints unsuccessful
login attempts.
Do you want to continue? {y|n}: y
cluster1::*>
```

The following command prompts system administrator to enter password and encrypt it with the hashing algorithm supported by releases earlier than Data ONTAP 9.0.

```
cluster1::*> security login password prepare-to-downgrade -disable-feature-set 9.0.0
Warning: If your password is not encrypted with an encryption type supported by
releases earlier than Data ONTAP 9.0.0, this command will prompt you
for a new password and encrypt it using a supported encryption type
on
each cluster or at each site in a MetroCluster configuration. In a
MetroCluster configuration, this command must be run on both sites.
The password for all other users are marked as "expired" and
changed to an internally generated password. The administrator must change
the passwords for all users before the users can login. The users are
prompted to change their password upon login.
Do you want to continue? {y|n}:

Enter a new password:
Enter it again:

cluster1::*>
```

## security login password

Modify a password for a user

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **security login password** command resets the password for a specified user. The command prompts you for the user's old and new password.

## Parameters

### **-vserver <vserver name> - Vserver**

This optionally specifies the Vserver name of the login method.

### **-username <text> - Username**

This optionally specifies the user name whose password is to be changed. If you do not specify a user, the command defaults to the user name you are currently using.

## Examples

The following command initiates a password change for the 'admin' user account of the 'vs' Vserver.

```
cluster1::> security login password -username admin -vserver vs
```

The following command initiates a password change for the 'vs' Vserver user account named 'admin'. The new password will be encrypted by using the SHA512 password-hashing algorithm.

```
cluster1::*> security login password -username admin -vserver vs -hash-function sha512
```

The following command initiates a password change for the 'vs' Vserver user account named 'admin'. The new password will be encrypted by using the SHA256 password-hashing encryption algorithm.

```
cluster1::*> security login password -username admin -vserver vs -hash-function sha256
```

## security login show

Show user login methods

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **security login show** command displays the following information about user login methods:

- User name
- Application (amqp, console, http, ontapi, rsh, snmp, service-processor, ssh, or telnet)
- Authentication method (community, password, publickey, or usm)
- Role name
- Whether the account is locked
- Whether the user name refers to **nsswitch** group

- Password hash function
- LDAP fastbind authentication

## Parameters

### { [-fields <fieldname>, ... ] }

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

### [ [-instance ] ] }

If you specify the **-instance** parameter, the command displays detailed information about all fields.

### [ -vserver <vserver name> ] - Vserver

Displays the login methods that match the specified Vserver name.

### [ -user-or-group-name <text> ] - User Name or Group Name

Displays the login methods that match this parameter value. Value can be a user name or Active Directory, LDAP, or NIS group name.

### [ -application <text> ] - Application

Displays the login methods that match the specified application type. Possible values include amqp, console, http, ontapi, rsh, snmp, service-processor, ssh, and telnet.

### [ -authentication-method <text> ] - Authentication Method

Displays the login methods that match the specified authentication method. Possible values include the following:

- cert - SSL certificate authentication
- community - SNMP community strings
- domain - Active Directory authentication
- nsswitch - LDAP or NIS authentication
- password - Password
- publickey - Public-key authentication
- usm - SNMP user security model
- saml - SAML authentication

### [ -remote-switch-ipaddress <IP Address> ] - Remote Switch IP Address

Displays the login methods that match the specified IP address of the remote switch. The remote switch could be a cluster switch monitored by cluster switch health monitor (CSHM) or a Fibre Channel (FC) switch monitored by MetroCluster health monitor (MCC-HM). This parameter is applicable only when the application is **snmp** and authentication method is **usm** (SNMP user security model).

**[-role <text>] - Role Name**

Displays the login methods that match the specified role.

**[-is-account-locked {yes|no}] - Account Locked**

Displays the login methods that match the specified account lock status.

**[-comment <text>] - Comment Text**

Displays the login methods that match the specified comment text.

**[-is-ns-switch-group {yes|no}] - Whether Ns-switch Group**

This specifies whether **user-or-group-name** is an LDAP or NIS group. Possible values are yes or no.

**[-hash-function {sha512|sha256}] - Password Hash Function**

Displays the login methods that match the specified password-hashing algorithm. Possible values are:

- sha512 - Secure hash algorithm (512 bits)
- sha256 - Secure hash algorithm (256 bits)
- md5 - Message digest algorithm (128 bits)

**[-second-authentication-method {none|publickey|password|nsswitch}] - Second Authentication Method2**

Displays the login methods that match the specified authentication method to be used as the second factor. Possible values include the following:

- password - Password
- publickey - Public-key authentication
- nsswitch - NIS or LDAP authentication
- none - default value

**[-is-ldap-fastbind {yes|no}] - LDAP Fastbind Authentication**

Displays the authentication methods that are LDAP fastbind.

## Examples

The example below illustrates how to display information about all user login methods:

```
cluster1::> security login show
```

```
Vserver: cluster1
```

User/Group Name	Application	Authentication Method	Role Name	Acct Locked	Second Authentication Method
admin	amqp	password	admin	no	none
admin	console	password	admin	no	none
admin	http	password	admin	no	none

```

admin      ontapi      password    admin       no      none
admin      service-processor
           password    admin       no      none
admin      ssh         password    admin       no      none
autosupport console     password    autosupport no      none

```

Vserver: vs1.netapp.com

User/Group Name	Application	Authentication Method	Role Name	Acct Locked	Second Authentication Method
vsadmin	http	password	vsadmin	yes	none
vsadmin	ontapi	password	vsadmin	yes	none
vsadmin	ssh	password	vsadmin	yes	none

9 entries were displayed.

## security login unlock

Unlock a user account with password authentication method

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **security login unlock** command unlocks a specified account, enabling it to access the management interface.

### Parameters

**-vserver <vserver name> - Vserver**

This optionally specifies the Vserver to which the user account belongs.

**-username <text> - Username**

This specifies the user name of the account that is to be unlocked.

### Examples

The following command unlocks a user account named *jdoue* which belongs to the Vserver *vs1*.

```
cluster1::> security login unlock -vserver vs1 -username jdoue
```

## security login whoami

Show the current user and role of this session

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **security login whoami** command displays the name and role of the user logged in at the current console session. It takes no options or other parameters.

## Examples

The following example shows that the current session is logged in by using the 'admin' user account:

```
cluster1::> whoami
                (security login whoami)
User: admin
Role: admin
```

# security login banner modify

Modify the login banner message

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **security login banner modify** command modifies the login banner. The login banner is printed just before the authentication step during the SSH and console device login process.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

Use this parameter to specify the Vserver whose banner will be modified. Use the name of the cluster admin Vserver to modify the cluster-level message. The cluster-level message is used as the default for data Vservers that do not have a message defined.

**{ [-message <text>] - Login Banner Message**

This optional parameter can be used to specify a login banner message. If the cluster has a login banner message set, the cluster login banner will be used by all data Vservers as well. Setting a data Vserver's login banner will override the display of the cluster login banner. To reset a data Vserver's login banner to use the cluster login banner, use this parameter with the value **"-"**.

If you use this parameter, the login banner cannot contain newlines (also known as end of lines (EOLs) or line breaks). To enter a login banner message with newlines, do not specify any parameter. You will be prompted to enter the message interactively. Messages entered

interactively can contain newlines.

Non-ASCII characters must be provided as Unicode UTF-8.

### **[`-uri` {(ftp|http|https)://(hostname|IPv4 Address|['IPv6 Address'])...}] - Download URI for the Banner Message }**

Use this parameter to specify the URI from where the login banner will be downloaded. Note that the message must not exceed 2048 bytes in length. Non-ASCII characters must be provided as Unicode UTF-8.

## Examples

This example shows how to enter a login banner interactively:

```
cluster1::> security login banner modify
Enter the login banner for Vserver "cluster1".
Max size: 2048. Enter a blank line to terminate input. Press Ctrl-C to abort.
0         1         2         3         4         5         6         7         8
1234567890123456789012345678901234567890123456789012345678901234567890
Authorized users only!
cluster1::>
```

# security login banner show

Display the login banner message

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `security login banner show` command displays the login banner.

## Parameters

**[`-fields` <fieldname>,...]**

If you specify the `-fields <fieldname>`, ... parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

**[`-instance` ]}**

If you specify the `-instance` parameter, the command displays detailed information about all fields.

**[`-vserver` <Vserver Name>] - Vserver Name**

Selects login banners that match the specified value. Use the name of the admin Vserver to

specify the cluster-level login banner.

### **[-message <text>] - Login Banner Message**

Selects login banners that match the specified value. By default, this command will not display unconfigured, or empty, login banners. To display all banners, specify `-message`*``.

## Examples

The following shows sample output from this command:

```
cluster1::> security login banner show
Message
-----
Authorized users only!
cluster1::>
```

## security login domain-tunnel create

Add authentication tunnel Vserver for administrative Vserver

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command establishes a gateway (tunnel) for authenticating Windows Active Directory (AD) domain users' access to the cluster.

Before using this command to establish the tunnel, the following must take place:

- You must use the [security login create](#) command to create one or more AD domain user accounts that will be granted access to the cluster.
- The `-authmethod` parameter of the [security login create](#) command must be set to 'domain'.
- The `-username` parameter of the [security login create](#) command must be set to a valid AD domain user account that is defined in a Windows Domain Controller's Active Directory. The user account must be specified in the format of `<domainname>\<username>`, where "domainname" is the name of the CIFS domain server.
- You must identify or create a CIFS-enabled data Vserver that will be used for Windows authentication with the Active Directory server. This Vserver is the tunnel Vserver, and it must be running for this command to succeed.

Only one Vserver can be used as the tunnel. If you attempt to specify more than one Vserver for the tunnel, Data ONTAP returns an error. If the tunnel Vserver is stopped or deleted, AD domain users' authentication requests to the cluster will fail.

## Parameters

### **-vserver <vserver> - Authentication Tunnel Vserver**

This parameter specifies a data Vserver that has been configured with CIFS. This Vserver will be used as the tunnel for authenticating AD domain users' access to the cluster.

## Examples

The following commands create an Active Directory domain user account ('DOMAIN1\Administrator') for the 'cluster1' cluster, create a data Vserver ('vs'), create a CIFS server ('vscifs') for the Vserver, and specify 'vs' as the tunnel for authenticating the domain user access to the cluster.

```
cluster1::> security login create -vserver cluster1 -username DOMAIN1\Administrator
-application ssh -authmethod domain -role admin
  cluster1::> vserver create -vserver vs -rootvolume vol -aggregate aggr -rootvolume
-security-style mixed
  cluster1::> vserver cifs create -vserver vs -cifs-server vscifs -domain
companyname.example.com -ou CN=Computers
  cluster1::> security login domain-tunnel create -vserver vs
```

## Related Links

- [security login create](#)

# security login domain-tunnel delete

Delete authentication tunnel Vserver for administrative Vserver

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **security login domain-tunnel delete** command deletes the tunnel established by the [security login domain-tunnel create](#) command. An error message will be generated if no tunnel exists.

## Examples

The following command deletes the tunnel established by [security login domain-tunnel create](#) .

```
cluster1::> security login domain-tunnel delete
```

## Related Links

- [security login domain-tunnel create](#)

# security login domain-tunnel modify

Modify authentication tunnel Vserver for administrative Vserver

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `security login domain-tunnel modify` command modifies or replaces the tunnel Vserver. If a tunnel Vserver is not already specified, it sets the current tunnel Vserver with this Vserver, otherwise, it replaces the current tunnel Vserver with the Vserver that you specify. If the tunnel Vserver is changed, authentication requests via previous Vserver will fail. See [security login domain-tunnel create](#) for more information.

## Parameters

### `[-vserver <vserver>]` - Authentication Tunnel Vserver

This parameter specifies a Vserver that has been configured with CIFS and is associated with a Windows Domain Controller's Active Directory authentication. This Vserver will be used as an authentication tunnel for login accounts so that they can be used with administrative Vservers.

## Examples

The following command modifies the tunnel Vserver for administrative Vserver.

```
cluster1::> security login domain-tunnel modify -vserver vs
```

## Related Links

- [security login domain-tunnel create](#)

# security login domain-tunnel show

Show authentication tunnel Vserver for administrative Vserver

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `security login domain-tunnel show` command shows the tunnel Vserver that was specified by the [security login domain-tunnel create](#) or [security login domain-tunnel modify](#) command.

## Examples

The example below shows the tunnel Vserver, `vs`, that is currently used as an authentication tunnel. The output informs you that the table is currently empty if tunnel Vserver has not been specified.

```
cluster1::> security login domain-tunnel show
Tunnel Vserver: vs
```

# security login motd modify

Modify the message of the day

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `security login motd modify` command updates the message of the day (MOTD).

There are two categories of MOTDs: the cluster-level MOTD and the data Vserver-level MOTD. A user logging in to a data Vserver's clustershell will potentially see two messages: the cluster-level MOTD followed by the Vserver-level MOTD for that Vserver. The cluster administrator can enable or disable the cluster-level MOTD on a per-Vserver basis. If the cluster administrator disables the cluster-level MOTD for a Vserver, a user logging into the Vserver will not see the cluster-level message. Only a cluster administrator can enable or disable the cluster-level message.

## Parameters

**-vserver <Vserver Name> - Vserver Name**

Use this parameter to specify the Vserver whose MOTD will be modified. Use the name of the cluster admin Vserver to modify the cluster-level message.

**{ [-message <text>] - Message of the Day (MOTD)**

This optional parameter can be used to specify a message. If you use this parameter, the MOTD

cannot contain newlines (also known as end of lines (EOLs) or line breaks). If you do not specify any parameter other than the **-vserver** parameter, you will be prompted to enter the message interactively. Messages entered interactively can contain newlines. Non-ASCII characters must be provided as Unicode UTF-8.

The message may contain dynamically generated content using the following escape sequences:

- **\** - A single backslash character.
- **\b** - No output: supported for compatibility with Linux only.
- **\C** - Cluster name.
- **\d** - Current date as set on the login node.
- **\t** - Current time as set on the login node.
- **\I** - Incoming LIF IP address (prints 'console' for a console login).
- **\l** - Login device name (prints 'console' for a console login).
- **\L** - Last login for the user on any node in the cluster.
- **\m** - Machine architecture.
- **\n** - Node or data Vserver name.
- **\N** - Name of user logging in.
- **\o** - Same as \O. Provided for Linux compatibility.
- **\O** - DNS domain name of the node. Note that the output is dependent on the network configuration and may be empty.
- **\r** - Software release number.
- **\s** - Operating system name.
- **\u** - Number of active clustershell sessions on the local node. For the cluster admin: all clustershell users. For the data Vserver admin: only active sessions for that data Vserver.
- **\U** - Same as \u, but has 'user' or 'users' appended.
- **\v** - Effective cluster version string.
- **\W** - Active sessions across the cluster for the user logging in ('who').

A backslash followed by any other character is emitted as entered.

#### **[ -uri {(ftp|http|https)://(hostname|IPv4 Address|['IPv6 Address'])...} - Download URI for the MOTD }**

Use this parameter to specify the URI from where the message of the day will be downloaded. Note that the message must not exceed 2048 bytes in length. Non-ASCII characters must be provided as Unicode UTF-8.

#### **[ -is-cluster-message-enabled {true|false} ] - Is Cluster-level Message Enabled?**

Use this parameter to enable or disable the display of the cluster-level MOTD for the specified Vserver.

## Examples

This example shows how to enter a MOTD interactively:

```
cluster1::> security login motd modify -vserver vs0

Enter the message of the day for Vserver "vs0".
Max size: 2048. Enter a blank line to terminate input. Press Ctrl-C to abort.
0      1      2      3      4      5      6      7      8
1234567890123456789012345678901234567890123456789012345678901234567890
Welcome to the Vserver!
cluster1::>
```

## security login motd show

Display the message of the day

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **security login motd show** command displays information about the cluster-level and data Vserver clustershell message of the day (MOTD).

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-vserver <Vserver Name>] - Vserver Name**

Selects the message of the day entries that match this parameter value. Use the name of the cluster admin Vserver to see the cluster-level MOTD.

**[-message <text>] - Message of the Day (MOTD)**

Selects the message of the day entries that match this parameter value.

**[-is-cluster-message-enabled {true|false}] - Is Cluster-level Message Enabled?**

Selects the message of the day entries that match this parameter value.

## Examples

The following example displays all message of the day entries:

```
cluster1::> security login motd show
Vserver: cluster1
Is the Cluster MOTD Displayed?: true
Message
-----
The cluster is running normally.

Vserver: vs0
Is the Cluster MOTD Displayed?: true
Message
-----
Welcome to the Vserver!

2 entries were displayed.
```

## security login publickey create

Add a new public key

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

### Description

The **security login publickey create** associates an existing public key with a user account. This command requires that you enter a valid OpenSSH-formatted public key, a user name, index number, and optionally, a comment.

### Parameters

**-vserver <vserver name> - Vserver**

This parameter optionally specifies the Vserver of the user for whom you are adding the public key.

**-username <text> - Username**

This parameter specifies the name of the user for whom you are adding the public key. If you do not specify a user, the user named admin is specified by default.

**[-index <integer>] - Index**

This parameter specifies an index number for the public key. The default value is the next available index value, starting with zero if it is the first public key created for the user.

**-publickey <certificate> - Public Key**

This specifies the OpenSSH public key, which must be enclosed in double quotation marks.

**[-comment <text>] - Comment**

This optionally specifies comment text for the public key. Note that comment text should be enclosed in quotation marks.

## Examples

The following command associates a public key with a user named tsmith for Vserver vs1. The public key is assigned index number 5 and the comment text is "This is a new key".

```
cluster1::> security login publickey create -vserver vs1 -username tsmith -index 5
-publickey
"ssh-rsa AAAAB3NzaC1yc2EAAAABIwAAAIEAspH64CYbUsDQCdW22JnK6J
/vU9upnKzd2zAk9C1f7YaWRUAFNs2Qe5lUmQ3ldi8AD0Vfbr5T6HZPCixNAIza
FciDy7hgnmdj9eNGedGr/JNrftQbLD1hZybX+72DpQB0tYWBhe6eDJ1oPLob
ZBGfMlPXh8VjeU44i7W4+s0hG0E=tsmith@publickey.example.com"
-comment "This is a new key"
```

# security login publickey delete

Delete a public key

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **security login publickey delete** command deletes a public key for a specific user. To delete a public key, you must specify a user name and index number.

## Parameters

**-vserver <vserver name> - Vserver**

This parameter optionally specifies the Vserver of the user for whom you are adding the public key.

**-username <text> - Username**

This parameter specifies the name of the user for whom you are deleting a public key. If you do not specify a user, the user named admin is specified by default.

**-index <integer> - Index**

This parameter specifies an index number for the public key.

## Examples

The following command deletes the public key for the user named tsmith with the index number 5.

```
cluster1::> security login publickey delete -username tsmith -index 5
```

# security login publickey load-from-uri

Load one or more public keys from a URI

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **security login publickey load-from-uri** command loads one or more public keys from a Universal Resource Identifier (URI). To load public keys from a URI, you must specify a user name, the URI from which to load them, and optionally, whether you want to overwrite the existing public keys.

## Parameters

**-vserver <vserver name> - Vserver**

This parameter optionally specifies the Vserver for the user associated with the public keys.

**-username <text> - Username**

This parameter specifies the username for the public keys. If you do not specify a username, the username **"admin"** is used by default.

**-uri {(ftp|http|https)://(hostname|IPv4 Address|['IPv6 Address'])...} - URI to load from**

This parameter specifies the URI from which the public keys will be loaded.

**-overwrite {true|false} - Overwrite Entries**

This parameter optionally specifies whether you want to overwrite existing public keys. The default value for this parameter is **false**. If the value is **true** and you confirm to overwrite, then the existing public keys are overwritten with the new public keys. If you use the value **false** or do not confirm the overwrite, then newly loaded public keys are appended to the list of existing public keys using the next available index.

## Examples

The following command shows how to load public keys for the user named tsmith from the URI <ftp://ftp.example.com/identity.pub>. This user's existing public keys are not overwritten.

```
cluster1::> security login publickey load-from-uri -username tsmith
```

```
-uri ftp://ftp.example.com/identity.pub -overwrite false
```

The following command shows how to load public keys for the user named tsmith from the URI ftp:ftp://ftp.example.com/identity.pub. This user's existing public keys are overwritten if user entered the option 'y' or 'Y'. The user's existing public keys are not overwritten if user entered the option 'n' or 'N' and the newly loaded public keys are appended to the list of existing public keys using the next available index. The user and password credentials that you provide when you use this command are the credentials to access the server specified by the URI.

```
cluster1::> security login publickey load-from-uri -username  
tsmith -uri ftp://ftp.example.com/identity.pub -overwrite true -vserver vs0
```

```
Enter User:  
Enter Password:
```

```
Warning: You are about to overwrite the existing publickeys for the user  
"tsmith" in Vserver "vs0". Do you want to proceed? {y|n}:
```

## security login publickey modify

Modify a public key

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

### Description

The **security login publickey modify** command modifies a public key and optionally its comment text.

### Parameters

**-vserver <vserver name> - Vserver**

Specifies the Vserver for the user associated with the public key.

**-username <text> - Username**

Specifies the username for the public key. If you do not specify a username, the username 'admin' is used by default.

**-index <integer> - Index**

Specifies the index number of the public key. The index number of the public key can be found by using the [security login publickey show](#) command.

**[-publickey <certificate>] - Public Key**

Specifies the new public key. You must enclose the new public key in double quotation marks.

**[-comment <text>] - Comment**

Specifies the new comment text for the public key.

## Examples

The following command modifies the public key at index number 10 for the user named tsmith of Vserver vs1.

```
cluster1::> security login publickey modify -vserver vs1 -username tsmith -index 10
-publickey
"ssh-rsa
AAAAB3NzaC1yc2EAAAADAQABAAQAAAQAAAQDDDD+pFzFgV/2d1owKRFgym9K910H/u+BVTGitCtHteHyo8thmaXT

# security login publickey show

Display public keys

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `security login publickey show` command displays information about public keys.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[ [-instance ] ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-vserver <vserver name>] - Vserver**

Selects the public keys that match this parameter value.

**[-username <text>] - Username**

Selects the public keys that match this parameter value.

**[-index <integer>] - Index**

Selects the public keys that match this parameter value.

**[-publickey <certificate>] - Public Key**

Selects the public keys that match this parameter value.

**[-fingerprint <text>] - Hex Fingerprint**

Selects the public keys that match this parameter value.

**[-bubblebabble <text>] - Bubblebabble Fingerprint**

Selects the public keys that match this parameter value.

**[-comment <text>] - Comment**

Selects the public keys that match this parameter value.

## Examples

The example below displays public key information for the user named tsmith.

```
cluster1::> security login publickey show -username tsmith
UserName: tsmith Index: 5
Public Key:
ssh-rsa AAAAB3NzaC1yc2EAAAABIwAAAIEAAspH64CYbUsDQCdW22JnK6J

```

## security login rest-role create

Add a REST access control role

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `security login rest-role create` command creates a Representational State Transfer (REST) access-control role. A REST access-control role consists of a role name and an Application Programming Interface (API) to which the role has access. It optionally includes an access level (**none**, **readonly**, **read\_create**, **read\_modify**, **read\_create\_modify** or **all**) for the API. After you create a REST access-control role, you can apply it to a management-utility login account by using the [security login modify](#) or [security login create](#) commands.

## Parameters

**-vserver <vserver name> - Vserver**

This optionally specifies the Vserver name associated with the REST role.

**-role <text> - Role Name**

This specifies the REST role that is to be created.

**-api <text> - API Path**

This specifies the API to which the REST role has access. This API can be a resource-qualified endpoint. Currently, the only supported resource-qualified endpoints are the following:

- Snapshots APIs
- **/api/storage/volumes/{volume.uuid}/snapshots**
- File System Analytics APIs
- **/api/storage/volumes/{volume.uuid}/files**
- **/api/storage/volumes/{volume.uuid}/top-metrics/clients**
- **/api/storage/volumes/{volume.uuid}/top-metrics/directories**
- **/api/storage/volumes/{volume.uuid}/top-metrics/files**
- **/api/storage/volumes/{volume.uuid}/top-metrics/users**
- **/api/svm/svms/{svm.uuid}/top-metrics/clients**
- **/api/svm/svms/{svm.uuid}/top-metrics/directories**
- **/api/svm/svms/{svm.uuid}/top-metrics/files**
- **/api/svm/svms/{svm.uuid}/top-metrics/users**

In the above APIs, wildcard character **\*** could be used in place of **{volume.uuid}** or **{svm.uuid}** to denote **all** volumes or **all** SVMs, depending upon whether the REST endpoint references volumes or SVMs.

**-access {none|readonly|read\_create|read\_modify|read\_create\_modify|all} - Access Level**

This optionally specifies an access level for the REST role. Possible access level settings are **none**, **readonly**, **read\_create**, **read\_modify**, **read\_create\_modify** and **all**.

## Examples

The following command creates a REST access-control role named **admin** for the **vs1.example.com** Vserver. This REST role has an access-level of **all** for the **/api/storage/volumes** API.

```
cluster1::> security login rest-role create -role admin -api "/api/storage/volumes"
-access all -vserver vs1.example.com
cluster1::>
```

The following command creates a REST access-control role named **rest\_role1** for the **cluster1.example.com** administrative Vserver. This REST role has an access-level of **read\_create\_modify** for the **/api/snapmirror/policies** API.

```
cluster1::> security login rest-role create -role rest_role1 -api
"/api/snapmirror/policies" -access read_create_modify -vserver cluster1.example.com
cluster1::>
```

The following command creates a REST access-control role named **vs1\_role** for the **vs1.example.com** Vserver. This REST role has an access level of **readonly** for all snapshots on the volume with UUID **f8a541b5-b68c-11ea-9581-005056bbabe6**.

```
cluster1::> security login rest-role create -role vs1_role -api
"/api/storage/volumes/f8a541b5-b68c-11ea-9581-005056bbabe6/snapshots" -access readonly
-vserver vs1.example.com
Warning: Operating on an alias operates on the target of the specified alias:
        "volume snapshot"
cluster1::>
```

The following command creates a REST access-control role named **vs2\_role** for the **vs2.example.com** Vserver. This REST role has an access level of **readonly** for all files on the volume with UUID **15d489b5-1d40-11ec-992e-005056bba268**.

```
cluster1::> security login rest-role create -role vs2_role -api
"/api/storage/volumes/15d489b5-1d40-11ec-992e-005056bba268/files" -access readonly
-vserver vs2.example.com
cluster1::>
```

The following command creates a REST access-control role named **vs3\_role** for the **vs3.example.com** Vserver. This REST role has an access level of **read\_create\_modify** for all top-metrics directories on the SVM with UUID **881764b5-9ea1-11ec-8771-005056bb1a7c**.

```
cluster1::> security login rest-role create -role vs3_role -api
"/api/svm/svms/881764b5-9ea1-11ec-8771-005056bb1a7c/top-metrics/directories" -access
read_create_modify -vserver vs3.example.com
```

```
cluster1::>
```

## Related Links

- [security login modify](#)
- [security login create](#)

# security login rest-role delete

Delete a REST access control role

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **security login rest-role delete** command deletes a Representational State Transfer (REST) access-control role.

## Parameters

**-vserver <vserver name> - Vserver**

This optionally specifies the Vserver name associated with the REST role.

**-role <text> - Role Name**

This specifies the REST role that is to be deleted.

**-api <text> - API Path**

This specifies the Application Programming Interface (API) to which the REST role has access. This API can be a resource-qualified endpoint. Currently, the only supported resource-qualified endpoints are the following:

- Snapshots APIs
  - **/api/storage/volumes/{volume.uuid}/snapshots**
- File System Analytics APIs
  - **/api/storage/volumes/{volume.uuid}/files**
  - **/api/storage/volumes/{volume.uuid}/top-metrics/clients**
  - **/api/storage/volumes/{volume.uuid}/top-metrics/directories**
  - **/api/storage/volumes/{volume.uuid}/top-metrics/files**
  - **/api/storage/volumes/{volume.uuid}/top-metrics/users**
- SVM APIs
  - **/api/svm/svms/{svm.uuid}/top-metrics/clients**
  - **/api/svm/svms/{svm.uuid}/top-metrics/directories**

- `/api/svm/svms/{svm.uuid}/top-metrics/files`
- `/api/svm/svms/{svm.uuid}/top-metrics/users`

In the above APIs, wildcard character `*` could be used in place of `{volume.uuid}` or `{svm.uuid}` to denote **all** volumes or **\_all\_** SVMs, depending upon whether the REST endpoint references volumes or SVMs.

## Examples

The following command deletes a REST access-control role entry with the role name **readonly** and the API `/api/storage/volumes` from Vserver **vs.example.com**.

```
cluster1::> security login rest-role delete -role readonly -api "/api/storage/volumes"
-vserver vs.example.com
cluster1::>
```

The following command deletes a REST access-control role entry with the role name **vs1\_role** and the resource-qualified endpoint corresponding to all snapshots on the volume with UUID **0aa39ec1-b68d-11ea-9581-005056bbabe6** from Vserver **vs1.example.com**.

```
cluster1::> security login rest-role delete -role vs1_role -api
"/api/storage/volumes/0aa39ec1-b68d-11ea-9581-005056bbabe6/snapshots" -vserver
vs1.example.com
cluster1::>
```

The following command deletes a REST access-control role entry with the role name **vs2\_role** and the resource-qualified endpoint corresponding to all top-metrics clients on the volume with UUID **373eb9ef-1d40-11ec-992e-005056bba268** from Vserver **vs2.example.com**.

```
cluster1::> security login rest-role delete -role vs2_role -api
"/api/storage/volumes/373eb9ef-1d40-11ec-992e-005056bba268/top-metrics/clients"
-vserver vs2.example.com
cluster1::>
```

The following command deletes a REST access-control role entry with the role name **vs3\_role** and the resource-qualified endpoint corresponding to all top-metrics directories for the Vserver **vs3.example.com** with UUID **6dfeb2a7-9a16-11ec-819e-005056bb1a7c**.

```
cluster1::> security login rest-role delete -role vs3_role -api
"/api/svm/svms/6dfeb2a7-9a16-11ec-819e-005056bb1a7c/top-metrics/directories" -vserver
vs3.example.com
cluster1::>
```

# security login rest-role modify

Modify a REST access control role

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `security login rest-role modify` command modifies a Representational State Transfer (REST) access-control role.

## Parameters

**-vserver <vserver name> - Vserver**

This optionally specifies the Vserver name associated with the REST role.

**-role <text> - Role Name**

This specifies the REST role that is to be modified.

**-api <text> - API Path**

This specifies the Application Programming Interface (API) to which the REST role has access. This API can be a resource-qualified endpoint. Currently, the only supported resource-qualified endpoints are the following:

- Snapshots APIs
  - `/api/storage/volumes/{volume.uuid}/snapshots`
- File System Analytics APIs
  - `/api/storage/volumes/{volume.uuid}/files`
  - `/api/storage/volumes/{volume.uuid}/top-metrics/clients`
  - `/api/storage/volumes/{volume.uuid}/top-metrics/directories`
  - `/api/storage/volumes/{volume.uuid}/top-metrics/files`
  - `/api/storage/volumes/{volume.uuid}/top-metrics/users`
- SVM APIs
  - `/api/svm/svms/{svm.uuid}/top-metrics/clients`
  - `/api/svm/svms/{svm.uuid}/top-metrics/directories`
  - `/api/svm/svms/{svm.uuid}/top-metrics/files`
  - `/api/svm/svms/{svm.uuid}/top-metrics/users`

In the above APIs, wildcard character `*` could be used in place of `{volume.uuid}` or `{svm.uuid}` to denote **all** volumes or **all** SVMs, depending upon whether the REST endpoint references volumes or SVMs.

**[-access {none|readonly|read\_create|read\_modify|read\_create\_modify|all}] - Access Level**

This specifies a new access level for the REST role. Possible access level settings are **none** ,

**readonly**, **read\_create**, **read\_modify**, **read\_create\_modify** and **all**.

## Examples

The following command modifies a REST access-control role with the role name **readonly** and the API **/api/storage/volumes** to have the access level **readonly** for Vserver **vs.example.com** :

```
cluster1::> security login rest-role modify -role readonly -api "/api/storage/volumes"
-access readonly -vserver vs.example.com
cluster1::>
```

The following command modifies a REST access-control role with the role name **rest\_role1** and the API **/api/snapmirror/policies** to have the access level **read\_create** for Vserver **cluster1.example.com** :

```
cluster1::> security login rest-role modify -role rest_role1 -api
"/api/snapmirror/policies" -access read_create -vserver cluster1.example.com
cluster1::>
```

The following command modifies a REST access-control role with the role name **vs1\_role** and the resource-qualified endpoint **/api/storage/volumes/\*/snapshots** to have the access level **readonly** for Vserver **vs1.example.com** :

```
cluster1::> security login rest-role modify -role vs1_role -api
"/api/storage/volumes/*/snapshots" -access readonly -vserver vs1.example.com
cluster1::>
```

The following command modifies a REST access-control role with the role name **vs2\_role** and the resource-qualified endpoint **/api/storage/volumes/4d383f47-1d40-11ec-81af-005056bb3eae/top-metrics/users** to have the access level **none** for Vserver **vs2.example.com** :

```
cluster1::> security login rest-role modify -role vs2_role -api
"/api/storage/volumes/4d383f47-1d40-11ec-81af-005056bb3eae/top-metrics/users" -access
none -vserver vs2.example.com
cluster1::>
```

The following command modifies a REST access-control role with the role name **vs3\_role** and the resource-qualified endpoint **/api/svm/svms/6dfeb406-9a16-11ec-819e-005056bb1a7c/top-metrics/files** to have the access level **read\_modify** for Vserver **vs3.example.com** :

```
cluster1::> security login rest-role modify -role vs3_role -api
"/api/svm/svms/6dfeb406-9a16-11ec-819e-005056bb1a7c/top-metrics/files" -access
read_modify -vserver vs3.example.com
cluster1::>
```

The following command modifies a REST access-control role with the role name **vs3\_role2** and the wildcard resource-qualified endpoint **/api/svm/svms/\*/top-metrics/clients** to have the access level **readonly** for Vserver **vs3.example.com** :

```
cluster1::> security login rest-role modify -role vs3_role2 -api "/api/svm/svms/*/top-
metrics/clients" -access readonly -vserver vs3.example.com
cluster1::>
```

## security login rest-role show

Show REST access control roles

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **security login rest-role show** command displays the following information about Representational State Transfer (REST) access-control roles:

- Vserver
- Role name
- Application Programming Interface (API) to which the REST role has access
- Access Level (**none** , **readonly** , **read\_create** , **read\_modify** , **read\_create\_modify** , or **all** )

### Parameters

{ [-fields <fieldname>, ... ] }

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

[ [-instance ] ] }

If you specify the **-instance** parameter, the command displays detailed information about all fields.

[ -vserver <vserver name> ] - Vserver

Selects the REST roles that match this parameter value.

[ -role <text> ] - Role Name

Selects the REST roles that match this parameter value. If this parameter and the **-api** parameter are both used, the command displays detailed information about the specified REST access-control role.

[ -api <text> ] - API Path

Selects the REST roles that match this parameter value. If this parameter and the **-role** parameter

are both used, the command displays detailed information about the specified REST access-control role. This API can be a resource-qualified endpoint. Currently, the only supported resource-qualified endpoints are the following:

- Snapshots APIs
- **/api/storage/volumes/{volume.uuid}/snapshots**
- File System Analytics APIs
- **/api/storage/volumes/{volume.uuid}/files**
- **/api/storage/volumes/{volume.uuid}/top-metrics/clients**
- **/api/storage/volumes/{volume.uuid}/top-metrics/directories**
- **/api/storage/volumes/{volume.uuid}/top-metrics/files**
- **/api/storage/volumes/{volume.uuid}/top-metrics/users**
- **/api/svm/svms/{svm.uuid}/top-metrics/clients**
- **/api/svm/svms/{svm.uuid}/top-metrics/directories**
- **/api/svm/svms/{svm.uuid}/top-metrics/files**
- **/api/svm/svms/{svm.uuid}/top-metrics/users**

In the above APIs, wildcard character **\*** could be used in place of **{volume.uuid}** or **{svm.uuid}** to denote **all** volumes or **all** SVMs, depending upon whether the REST endpoint references volumes or SVMs.

**[-access {none|readonly|read\_create|read\_modify|read\_create\_modify|all}] - Access Level**

Selects the roles that match this parameter value.

## Examples

The example below displays information about all REST access-control roles:

```
cluster1::> security login rest-role show
Role                Access
-----
Vserver            Name          API           Level
-----
vs                  vsrole1      /api          none
vs                  vsrole1      /api/storage/volumes/f8a541b5-b68c-11ea-9581-
005056bbabe6/files
                                                           all
vs                  vsrole1      /api/storage/volumes/f8a541b5-b68c-11ea-9581-
005056bbabe6/snapshots
                                                           readonly
vs                  vsrole1      /api/storage/volumes/843b87f9-2f5e-11ec-9524-
005056bb0bee/snapshots
                                                           read_create
vs                  vsrole1      /api/svm/svms/843b87f9-2f5e-11ec-9524-
005056bb0bee/top-metrics/clients
```

```

cluster1      readonly  /api/storage  read_create
cluster1      custom   /api/cluster  none
cluster1      custom   /api/cluster  read_modify
cluster1      custom   /api/security/accounts
cluster1      custom   /api/storage/volumes/*/top-metrics/users
cluster1      custom   /api/storage/volumes/*/snapshots
cluster1::>

```

## security login rest-role expanded-rest-roles modify

Modify the status of Expanded REST roles for granular resource control feature

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

The `security login rest-role expanded-rest-roles modify` command enables or disables **Expanded REST roles for granular resource control** feature.

### Parameters

`[-is-enabled {true|false}] - Is Enabled?`

This parameter specifies whether the **Expanded REST roles for granular resource control** feature is enabled or disabled. The default value is **true** i.e. the feature is enabled by default.

### Examples

The following command disables the **Expanded REST roles for granular resource control** feature.

```

cluster1::*> security login rest-role expanded-rest-roles modify -is-enabled false
cluster1::*>

```

## security login rest-role expanded-rest-roles show

Show the status of Expanded REST roles for granular resource control feature

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `security login rest-role expanded-rest-roles show` command specifies whether the **Expanded REST roles for granular resource control** feature is enabled (**true**) or disabled (**false**).

## Examples

The command below specifies that the **Expanded REST roles for granular resource control** feature is enabled.

```
cluster1::> security login rest-role expanded-rest-roles show

Is Enabled? true
```

## security login role create

Add an access control role

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `security login role create` command creates an access-control role. An access-control role consists of a role name and a command or directory to which the role has access. It optionally includes an access level (none, readonly, or all) and a query that applies to the specified command or command directory. After you create an access-control role, you can apply it to a management-utility login account by using the [security login modify](#) or [security login create](#) commands.

## Parameters

**-vserver <vserver name> - Vserver**

This optionally specifies the Vserver name associated with the role.

**-role <text> - Role Name**

This specifies the role that is to be created.

**-cmddirname <text> - Command / Directory**

This specifies the command or command directory to which the role has access. The command or command directory must be specified either within double quotes or inside curly brackets. To specify the default setting, use the special value "DEFAULT".

**[-access {none|readonly|read\_create|read\_modify|read\_create\_modify|all}] - Access Level**

This optionally specifies an access level for the role. Possible access level settings are none, readonly, and all. The default setting is **all**.

### **[-query <query>] - Query**

This optionally specifies the object that the role is allowed to access. The query object must be applicable to the command or directory name specified by `-cmddirname`. The query object must be enclosed in double quotation marks (""), and it must be a valid field name.

## Examples

The following command creates an access-control role named "admin" for the vs1.example.com Vserver. The role has all access to the "volume" command but only within the "aggr0" aggregate.

```
cluster1::> security login role create -role admin -cmddirname volume -query "-aggr  
aggr0" -access all -vserver vs1.example.com
```

## Related Links

- [security login modify](#)
- [security login create](#)

# security login role delete

Delete an access control role

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `security login role delete` command deletes an access-control role.

## Parameters

### **-vserver <vserver name> - Vserver**

This optionally specifies the Vserver name associated with the role.

### **-role <text> - Role Name**

This specifies the role that is to be deleted.

### **-cmddirname <text> - Command / Directory**

This specifies the command or command directory to which the role has access. To specify the default setting, use the special value "`DEFAULT``".

## Examples

The following command deletes an access-control role with the role name `readonly` and the

command access "volume" for Vserver vs.example.com.

```
cluster1::> security login role delete -role readonly -cmddirname volume -vserver vs.example.com
```

## security login role modify

Modify an access control role

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **security login role modify** command modifies an access-control role.

### Parameters

**-vserver <vserver name> - Vserver**

This optionally specifies the Vserver name associated with the role.

**-role <text> - Role Name**

This specifies the role that is to be modified.

**-cmddirname <text> - Command / Directory**

This specifies the command or command directory to which the role has access. To specify the default setting for a role, use the special value **"DEFAULT"**. This value can be modified only for the roles created for the admin Vserver.

**[-access {none|readonly|read\_create|read\_modify|read\_create\_modify|all}] - Access Level**

This optionally specifies a new access level for the role. Possible access level settings are none, readonly, and all. The default setting is **all**.

**[-query <query>] - Query**

This optionally specifies the object that the role is allowed to access. The query object must be applicable to the command or directory name specified by **-cmddirname**. The query object must be enclosed in double quotation marks (""), and it must be a valid field name.

### Examples

The following command modifies an access-control role with the role name **readonly** and the command access "volume" to have the access level **readonly** for Vserver **vs.example.com**:

```
cluster1::> security login role modify -role readonly -cmddirname volume -access readonly -vserver vs.example.com
```

# security login role show-ontapi

Display the mapping between Data ONTAP APIs and CLI commands

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **security login role show-ontapi** command displays Data ONTAP APIs (ONTAPIs) and the CLI commands that they are mapped to.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[ -ontapi <text> ] - ONTAPI Name**

Use this parameter to view the corresponding CLI command for the specified API.

**[ -command <text> ] - CLI Command**

Use this parameter to view the corresponding API or APIs for the specified CLI command.

## Examples

The following command displays all Data ONTAP APIs and their mapped CLI commands:

```
cluster1::> security login role show-ontapi
ONTAPI                               Command
-----
aggr-add                             storage aggregate add-disks
aggr-check-spare-low                 storage aggregate check_spare_low
aggr-create                          storage aggregate create
aggr-destroy                          storage aggregate delete
aggr-get-filer-info                  aggr
aggr-get-iter                        storage aggregate show-view
aggr-offline                         storage aggregate offline
aggr-online                          storage aggregate online
aggr-options-list-info               storage aggregate show
aggr-rename                          storage aggregate rename
aggr-restrict                        storage aggregate restrict
```

```

aggr-set-option          storage aggregate modify
autosupport-budget-get  system node autosupport budget show
autosupport-budget-get-iter system node autosupport budget show
autosupport-budget-get-total-records
                           system node autosupport budget show
autosupport-budget-modify system node autosupport budget modify
autosupport-config-get  system node autosupport show
autosupport-config-get-iter system node autosupport show
autosupport-config-get-total-records
                           system node autosupport show
autosupport-config-modify system node autosupport modify
Press <space> to page down, <return> for next line, or 'q' to quit...

```

The following example displays all Data ONTAP APIs which are mapped to the specified CLI command:

```

cluster1::> security login role show-ontapi -command version
ONTAPI          Command
-----
system-get-ontapi-version  version
system-get-version        version
2 entries were displayed.

```

The following example displays the CLI command that is mapped to the specified Data ONTAPI API:

```

cluster1::> security login role show-ontapi -ontapi aggr-create

ONTAPI Name: aggr-create
Command: storage aggregate create

```

## security login role show

Show access control roles

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **security login role show** command displays the following information about access-control roles:

- Role name
- Command or command directory to which the role has access
- Access level (none, read-only, or all)

- Query (detailed view only)

## Parameters

### { [-fields <fieldname>, ... ] }

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

### [ [-instance ] ] }

If you specify the **-instance** parameter, the command displays detailed information about all fields.

### [ -vserver <vserver name> ] - Vserver

Selects the roles that match this parameter value.

### [ -role <text> ] - Role Name

Selects the roles that match this parameter value. If this parameter and the **-cmddirname** parameter are both used, the command displays detailed information about the specified access-control role.

### [ -cmddirname <text> ] - Command / Directory

Selects the roles that match this parameter value. If this parameter and the **-role** parameter are both used, the command displays detailed information about the specified access-control role.

### [ -access { none|readonly|read\_create|read\_modify|read\_create\_modify|all } ] - Access Level

Selects the roles that match this parameter value.

### [ -query <query> ] - Query

Selects the roles that match this parameter value.

## Examples

The example below displays information about all access-control roles:

```
cluster1::> security login role show
```

Vserver	RoleName	Command/Directory	Query	AccessLevel
vs	vsadmin	DEFAULT		none
vs	vsadmin	dashboard health vserver		readonly
vs	vsadmin	job		readonly
vs	vsadmin	job schedule		none
vs	vsadmin	lun		all
vs	vsadmin	network connections		readonly
cluster1	admin	DEFAULT		all
cluster1	readonly	DEFAULT		readonly

cluster1	readonly	volume	none
----------	----------	--------	------

# security login role config modify

Modify local user account restrictions

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **security login role config modify** command modifies user account and password restrictions.

For the password character restrictions documented below (uppercase, lowercase, digits, etc.), the term "characters" refers to ASCII-range characters only - not extended characters.

## Parameters

### **-vserver <vserver name> - Vserver**

This specifies the Vserver name associated with the profile configuration.

### **-role <text> - Role Name**

This specifies the role whose account restrictions are to be modified.

### **[-username-minlength <integer>] - Minimum Username Length Required**

This specifies the required minimum length of the user name. Supported values are 3 to 16 characters. The default setting is **3** characters.

### **[-username-alphanum {enabled|disabled}] - Username Alpha-Numeric**

This specifies whether a mix of alphabetic and numeric characters are required in the user name. If this parameter is enabled, a user name must contain at least one letter and one number. The default setting is **disabled**.

### **[-passwd-minlength <integer>] - Minimum Password Length Required**

This specifies the required minimum length of a password. Supported values are 3 to 64 characters. The default setting is **8** characters.

### **[-passwd-alphanum {enabled|disabled}] - Password Alpha-Numeric**

This specifies whether a mix of alphabetic and numeric characters is required in the password. If this parameter is enabled, a password must contain at least one letter and one number. The default setting is **enabled**.

### **[-passwd-min-special-chars <integer>] - Minimum Number of Special Characters Required in the Password**

This specifies the minimum number of special characters required in a password. Supported values are from 0 to 64 special characters. The default setting is **0**, which requires no special characters.

**[-passwd-expiry-time <unsigned32\_or\_unlimited>] - Password Expires In (Days)**

This specifies password expiration in days. A value of **0** means all passwords associated with the accounts in the role expire now. The default setting is **unlimited**, which means the passwords never expire.

**[-require-initial-passwd-update {enabled|disabled}] - Require Initial Password Update on First Login**

This specifies whether users must change their passwords when logging in for the first time. Initial password changes can be done only through SSH or serial-console connections. The default setting is **disabled**.

**[-max-failed-login-attempts <integer>] - Maximum Number of Failed Attempts**

This specifies the allowed maximum number of consecutive invalid login attempts. When the failed login attempts reach the specified maximum, the account is automatically locked. The default is **0**, which means failed login attempts do not cause an account to be locked.

**[-lockout-duration <integer>] - Maximum Lockout Period (Days)**

This specifies the number of days for which an account is locked if the failed login attempts reach the allowed maximum. The default is **0**, which means the accounts will be locked for 1 day.

**[-disallowed-reuse <integer>] - Disallow Last 'N' Passwords**

This specifies the number of previous passwords that are disallowed for reuse. The default setting is six, meaning that the user cannot reuse any of their last six passwords. The minimum allowed value is **6**.

**[-change-delay <integer>] - Delay Between Password Changes (Days)**

This specifies the number of days that must pass between password changes. The default setting is **0**.

**[-delay-after-failed-login <integer>] - Delay after Each Failed Login Attempt (Secs)**

This specifies the amount of delay observed by the system in seconds upon invalid login attempts. The default setting is **4** seconds.

**[-passwd-min-lowercase-chars <integer>] - Minimum Number of Lowercase Alphabetic Characters Required in the Password**

This specifies the minimum number of lowercase characters required in a password. Supported values are from 0 to 64 lowercase characters. The default setting is **0**, which requires no lowercase characters.

**[-passwd-min-uppercase-chars <integer>] - Minimum Number of Uppercase Alphabetic Characters Required in the Password**

This specifies the minimum number of uppercase characters required in a password. Supported values are from 0 to 64 uppercase characters. The default setting is **0**, which requires no uppercase characters.

**[-passwd-min-digits <integer>] - Minimum Number of Digits Required in the Password**

This specifies the minimum number of digits required in a password. Supported values are from 0

to 64 digits characters. The default setting is **0** , which requires no digits.

### **[-passwd-expiry-warn-time <unsigned32\_or\_unlimited>] - Display Warning Message Days Prior to Password Expiry (Days)**

This specifies the warning period for password expiry in days. A value of **0** means warn user about password expiry upon every successful login. The default setting is **unlimited** , which means never warn about password expiry.

### **[-account-expiry-time <unsigned32\_or\_unlimited>] - Account Expires in (Days)**

This specifies account expiration in days. The default setting is **unlimited** , which means the accounts never expire. The account expiry time must be greater than account inactive limit.

### **[-account-inactive-limit <unsigned32\_or\_unlimited>] - Maximum Duration of Inactivity before Account Expiration (Days)**

This specifies inactive account expiry limit in days. The default setting is **unlimited** , which means the inactive accounts never expire. The account inactive limit must be less than account expiry time.

## Examples

The following command modifies the user-account restrictions for an account with the role name admin for a Vserver named vs. The minimum size of the password is set to 12 characters.

```
cluster1::> security login role config modify -role admin -vserver vs
-passwd-minlength 12
```

# security login role config reset

Reset RBAC characteristics supported on releases later than Data ONTAP 8.1.2

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **security login role config reset** command resets the following role based access control (RBAC) characteristics to their default values. The system prompts you to run this command if you revert to Data ONTAP 8.1.2 or earlier. If you do not reset these characteristics, the revert process will fail.

- Minimum number of special characters required in password ("0")
- Password-expiration time, in days ("unlimited")
- Whether the password must be changed at the initial login ("disabled")
- Maximum number of failed login attempts permitted before the account is locked out ("0")
- Number of days that the user account is locked out after the maximum number of failed login

attempts is reached ("0")

## Examples

The following command resets the above mentioned RBAC characteristics of all cluster and Vserver roles to their default values.

```
cluster1::> security login role config reset
```

# security login role config show

Show local user account restrictions

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **security login role config show** command displays the following information about account restrictions for management-utility user accounts:

- Role name **-role**
- Minimum size of the password, in characters **-passwd-minlength**
- Whether the password requires alphanumeric characters **-passwd-alphanum**
- Number of previous passwords that cannot be reused **-disallowed-reuse**
- Minimum number of days that must elapse before users can change their passwords **-change-delay**

You can display detailed information about the restrictions on a specific account by specifying the **-role** parameter. This adds the following information:

- Minimum length of the user name, in characters **-username-minlength**
- Whether the user name requires alphanumeric characters **-username-alphanum**
- Minimum length of the password, in characters **-passwd-minlength**
- Whether the password requires alphanumeric characters **-passwd-alphanum**
- Minimum number of special characters required in password **-passwd-min-special-chars**
- Minimum number of lowercase characters required in password **-passwd-min-lowercase-chars**
- Minimum number of uppercase characters required in password **-passwd-min-uppercase-chars**
- Minimum number of digits required in password **-passwd-min-digits**
- Minimum number of days that must elapse before users can change their passwords **-change-delay**
- Whether the password must be changed at the initial login **-require-initial-passwd-update**

- Password-expiration time, in days **-passwd-expiry-time**
- Display warning message days prior to password expiry **-passwd-expiry-warn-time**
- Number of previous passwords that cannot be reused **-disallowed-reuse**
- Maximum number of failed login attempts permitted before the account is locked out **-max-failed-login-attempts**
- Number of days for which the user account is locked after the maximum number of failed login attempts is reached **-lockout-duration**
- Account-expiration time, in days **-account-expiry-time**
- Maximum duration of inactivity before account expiration, in days **-account-inactive-limit**
- Delay after each failed login attempt, in secs **-delay-after-failed-login**

## Parameters

**{ [-fields <fieldname>,...]**

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[-instance ]}**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-vserver <vserver name>] - Vserver**

Selects the profile configurations that match this parameter value

**[-role <text>] - Role Name**

If this parameter is specified, the command displays detailed information about restrictions for the specified user account.

**[-username-minlength <integer>] - Minimum Username Length Required**

Selects the profile configurations that match this parameter value.

**[-username-alphanum {enabled|disabled}] - Username Alpha-Numeric**

Selects the profile configurations that match this parameter value. Enabled means a user name must contain both letters and numbers.

**[-passwd-minlength <integer>] - Minimum Password Length Required**

Selects the profile configurations that match this parameter value.

**[-passwd-alphanum {enabled|disabled}] - Password Alpha-Numeric**

Selects the profile configurations that match this parameter value. Enabled means a password must contain both letters and numbers.

**[-passwd-min-special-chars <integer>] - Minimum Number of Special Characters Required in the Password**

Selects the profile configurations that match this parameter value.

**[-passwd-expiry-time <unsigned32\_or\_unlimited>] - Password Expires In (Days)**

Selects the profile configurations that match this parameter value.

**[-require-initial-passwd-update {enabled|disabled}] - Require Initial Password Update on First Login**

Selects the profile configurations that match this parameter value.

**[-max-failed-login-attempts <integer>] - Maximum Number of Failed Attempts**

Selects the profile configurations that match this parameter value.

**[-lockout-duration <integer>] - Maximum Lockout Period (Days)**

Selects the profile configurations that match this parameter value.

**[-disallowed-reuse <integer>] - Disallow Last 'N' Passwords**

Selects the profile configurations that match this parameter value.

**[-change-delay <integer>] - Delay Between Password Changes (Days)**

Selects the profile configurations that match this parameter value.

**[-delay-after-failed-login <integer>] - Delay after Each Failed Login Attempt (Secs)**

Selects the profile configurations that match this parameter value.

**[-passwd-min-lowercase-chars <integer>] - Minimum Number of Lowercase Alphabetic Characters Required in the Password**

Selects the profile configurations that match this parameter value.

**[-passwd-min-uppercase-chars <integer>] - Minimum Number of Uppercase Alphabetic Characters Required in the Password**

Selects the profile configurations that match this parameter value.

**[-passwd-min-digits <integer>] - Minimum Number of Digits Required in the Password**

Selects the profile configurations that match this parameter value.

**[-passwd-expiry-warn-time <unsigned32\_or\_unlimited>] - Display Warning Message Days Prior to Password Expiry (Days)**

Selects the profile configurations that match this parameter value.

**[-account-expiry-time <unsigned32\_or\_unlimited>] - Account Expires in (Days)**

Selects the profile configurations that match this parameter value.

**[-account-inactive-limit <unsigned32\_or\_unlimited>] - Maximum Duration of Inactivity before Account Expiration (Days)**

Selects the profile configurations that match this parameter value.

## Examples

The example below displays restriction information about all user accounts:

```
cluster1::> security login role config show
----- Password Restrictions -----
Vserver      RoleName      Size AlphaNum NoReuse ChangeDelay
-----
vs           vsadmin       8  enabled      6      0 days
vs           vsadmin-protocol 8  enabled      6      0 days
vs           vsadmin-readonly 8  enabled      6      0 days
vs           vsadmin-volume 8  enabled      6      0 days
cluster1     admin         6  enabled      6      0 days
cluster1     readonly      6  enabled      6      0 days
```

## security multi-admin-verify modify

Modify multi-admin-verify settings

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **security multi-admin-verify modify** command is used to modify the Multi-Admin-Verify global settings.

### Parameters

#### **[-approval-groups <text>, ...] - List of Global Approval Groups**

This specifies the list of global approval groups which are inherited by the rule if the approval-groups is not provided for the rule. The default value is an empty list. The approval-groups should be defined to enable multi-admin verification. The supplied value replaces the list. You can create an approval-group by using the [security multi-admin-verify approval-group create](#) command.

#### **[-required-approvers <integer>] - Number of Required Approvers**

This specifies the required number of approvers to approve the request which is inherited by the rule if required-approvers is not provided for the rule. The default and minimum number of required approvers is 1.

#### **[-enabled {true|false}] - Is Multi-Admin-Verify Enabled**

This specifies the current state. Multi-admin verification is not required to enable the feature. However, it is required to disable the feature. The feature is disabled by default and the value is set to false.

**[-execution-expiry <[<integer>h][<integer>m][<integer>s]>] - Execution Expiry**

This is the amount of time that the authorized users have after a request is approved to execute the requested operation before the request expires. The default value is one hour (**1h**), the minimum supported value is one second (**1s**), and the maximum supported value is 14 days (**14d**).

**[-approval-expiry <[<integer>h][<integer>m][<integer>s]>] - Approval Expiry**

This is the amount of time that the approvers have after a new execution request is submitted to approve or disapprove the request before the request expires. The default value is one hour (**1h**), the minimum supported value is one second (**1s**), and the maximum supported value is 14 days (**14d**).

## Examples

This command changes the approval groups:

```
cluster1::> security multi-admin-verify modify -approval-groups group1, group2
```

This command changes the required number of approvers:

```
cluster1::> security multi-admin-verify modify -required-approvers 3
```

This command enables the feature. The default is false (disabled):

```
cluster1::> security multi-admin-verify modify -enabled true
```

This command changes the execution expiry:

```
cluster1::> security multi-admin-verify modify -execution-expiry 14d
```

This command changes the approval expiry:

```
cluster1::> security multi-admin-verify modify -approval-expiry 48h
```

## Related Links

- [security multi-admin-verify approval-group create](#)

# security multi-admin-verify show

Display multi-admin-verify configuration

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **security multi-admin-verify show** command displays the object store that contains the global setting values of the multi-admin-verify feature.

- **Is Enabled:** Displays the current state of the feature. This feature is, by default, disabled and the value is set to false.
- **Required Approvers:** Displays the required number of approvers to approve the ONTAP execution request. This is inherited by the rule if required-approvers is not provided for the rule. The default and minimum number of required approvers is 1.
- **Approval Expiry:** Displays the amount of time that the approvers have after a new execution request is submitted to approve or disapprove the request before the request expires.
- **Execution Expiry:** Displays the amount of time that the authorized users have after a request is approved to execute the requested operation before the request expires.
- **Approval Groups:** Displays the list of global approval groups. This will be in effect if the approval groups is not specified for a multi-admin-verify rule.

## Examples

The following example displays typical global settings information:

```
cluster1::> security multi-admin-verify show
Is      Required  Execution Approval Approval
Enabled Approvers Expiry    Expiry    Groups
-----
false   1          1h       1h        group1, group2
```

# security multi-admin-verify approval-group create

Create an Approval Group

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **security multi-admin-verify approval-group create** command creates an approval group for a specified Vserver for a specified list of ONTAP users.

## Parameters

### **-vserver <vserver> - Vserver**

This specifies the Vserver name to which the approval group is associated with. This is an optional parameter. This parameter defaults to a Cluster server and supports only Cluster servers.

### **-name <text> - Group Name**

This specifies the name of an approval group.

### **-approvers <text>, ... - Approvers**

This specifies the list of ONTAP users that are part of the approval group. Each specified user must belong to the specified Vserver.

### **[-email <mail address>, ...] - Email Addresses**

This specifies the email addresses that are notified when a request is created, approved, vetoed, or executed.

## Examples

The following example creates a new approval group named group1 with approver admin1 that is associated with the default Vserver cluster1:

```
cluster1::> security multi-admin-verify approval-group create -name group1 -approvers  
admin1
```

# security multi-admin-verify approval-group delete

Delete an Approval Group

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **security multi-admin-verify approval-group delete** command deletes the specified approval group.

## Parameters

### **-vserver <vserver> - Vserver**

This specifies the Vserver information to which the approval group is associated with. This is an optional parameter. This parameter defaults to Cluster server and supports only Cluster servers.

**-name <text> - Group Name**

This specifies the name of an approval group to be deleted.

## Examples

The following example deletes the approval group, group1:

```
cluster1::> security multi-admin-verify approval-group delete -name group1
```

# security multi-admin-verify approval-group modify

## Modify an Approval Group

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **security multi-admin-verify approval-group modify** command is used to modify attributes of an approval group.

## Parameters

**-vserver <vserver> - Vserver**

This specifies the Vserver name to which the approval group is associated with. This is an optional parameter. This parameter defaults to a Cluster server and supports only Cluster servers.

**-name <text> - Group Name**

This specifies the name of an approval group.

**[-approvers <text>,...] - Approvers**

This specifies the list of ONTAP users that are part of the approval group. Each specified user must belong to the specified Vserver.

**[-email <mail address>,...] - Email Addresses**

This specifies the email addresses that are notified when a request is created, approved, vetoed, or executed.

## Examples

This command changes the approvers:

```
cluster1::> security multi-admin-verify approval-group modify -name group1 -approvers  
admin1
```

# security multi-admin-verify approval-group replace

Add and/or remove approvers from the list

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `security multi-admin-verify approval-group replace` command is used to replace the list of approvers of an approval group.

## Parameters

### **-vserver <vserver> - Vserver**

This specifies the Vserver name to which the approval group is associated with. This is an optional parameter. This parameter defaults to Cluster server and supports only Cluster servers.

### **-name <text> - Group Name**

This specifies the name of the approval group whose approvers are to be replaced.

### **[-approvers-to-add <text>, ...] - New Approvers**

This specifies the list of ONTAP users that are to be added to the current list of approvers of the approval group.

### **[-approvers-to-remove <text>, ...] - Existing Approvers**

This specifies the list of ONTAP users that are to be removed from the current list of approvers of the approval group.

## Examples

The following example adds user `admin2` and removes user `admin` from the current approvers list, while `group1` is associated with the default Vserver:

```
cluster1::> security multi-admin-verify approval-group replace -name group1 -approvers  
-to-add admin2 -approvers-to-remove admin.
```

# security multi-admin-verify approval-group show

Display Approval Groups

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `security multi-admin-verify approval-group show` command displays information about approval groups and the users that are registered with each group.

## Parameters

`{ [-fields <fieldname>, ... ] }`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

`[ [-instance ] ] }`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-vserver <vserver>] - Vserver`

This specifies the Vserver name to which the approval group is associated with. This is an optional parameter. This parameter defaults to a Cluster server and supports only Cluster servers.

`[-name <text>] - Group Name`

This specifies the name of an approval group.

`[-approvers <text>, ...] - Approvers`

This specifies the list of ONTAP users that are part of the approval group. Each specified user must belong to the specified Vserver.

`[-email <mail address>, ...] - Email Addresses`

This specifies the email addresses that are notified when a request is created, approved, vetoed, or executed.

## Examples

The following example displays typical approval groups information:

```
cluster1::> security multi-admin-verify approval-group show
Vserver  Name                Approvers
-----
```

```
cluster1
  group1      admin
  group2      admin, admin1
2 entries were displayed.
```

## security multi-admin-verify request approve

Approve a request

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The `security multi-admin-verify request approve` command approves the specified request.

### Parameters

`-index <integer>` - Request Index

This allows the user to specify the index of the request to be approved.

### Examples

The following example approves the request with index 1:

```
cluster1::> security multi-admin-verify request approve -index 1
```

## security multi-admin-verify request create

Create a request

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

### Description

The `security multi-admin-verify request create` command creates a request for the specified ONTAP operation.

### Parameters

`[-index <integer>]` - Request Index

This specifies the index of the request which is automatically generated for each request.

**-operation <text> - Operation**

This specifies the ONTAP operation information for which the request is to be created.

**-query <query> - Query**

This identifies the object (or objects) upon which the user wants to apply the operation. Any field or query supported by the operation can be supplied.

**[-comment <text>] - Comment**

This is an optional parameter where users creating a request can provide comments related to the request.

**[-users-permitted <text>,...] - Users Permitted**

This is an optional parameter where a user creating the request can specify the list of ONTAP users who are permitted to perform the ONTAP operation specified by the request, once it is approved. If this parameter is not provided, then any user with default permissions to perform the ONTAP operation is allowed to perform the ONTAP operation specified by the request.

## Examples

The following example creates a new request for ONTAP operation volume delete which is applicable to objects of vserver vs0.

```
cluster1::> security multi-admin-verify request create -operation "volume delete"
-query "-vserver vs0"
```

The following example creates a new request for the ONTAP operation volume snapshot delete which is applicable to Vserver objects vs0 and volume v1. Users permitted to perform this operation on the specified subset of objects are user1 and user2:

```
cluster1::> security multi-admin-verify request create -operation "volume delete"
-query "-vserver vs0 -volume v1" -users-permitted user1, user2
```

# security multi-admin-verify request delete

Delete a request

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **security multi-admin-verify request delete** command deletes the specified request.

## Parameters

### **-index <integer>** - Request Index

This allows the user to specify the index of the request to be deleted.

## Examples

The following example deletes the request with index 1:

```
cluster1::> security multi-admin-verify request delete -index 1
```

# security multi-admin-verify request show-pending

Show only pending requests

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **security multi-admin-verify request show-pending** command displays information about multi-admin verification requests that are in the pending state.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[ -index <integer> ] - Request Index**

This specifies the index of the request.

**[ -operation <text> ] - Operation**

This specifies the ONTAP operation for which the request is created.

**[ -query <query> ] - Query**

This identifies the object (or objects) upon which the user wants to apply the operation.

**[-required-approvers <integer>] - Required Approvers**

This specifies the number of distinct users that are required to approve the request. A user can set the required-approvers to the ONTAP operation rule. If a user does not set the required-approvers to the rule, then the required-approvers from the global setting is applied.

**[-pending-approvers <integer>] - Pending Approvers**

This specifies the number of distinct users that are still required to approve the request for the request to be marked as approved.

**[-approval-expiry {MM/DD/YYYY HH:MM:SS | {1..7}days | {1..168}hours | PnDTnHnMnS | PnW}] - Approval Expiry**

This specifies the expiry information within which an approve or veto action is to be taken by the approvers from the time the request is submitted. Any authorized user can set the approval-expiry to the ONTAP operation rule. If the user does not set the approval-expiry to the rule, then the approval-expiry from the global setting is applied.

**[-execution-expiry {MM/DD/YYYY HH:MM:SS | {1..7}days | {1..168}hours | PnDTnHnMnS | PnW}] - Execution Expiry**

This specifies the expiry information within which an ONTAP operation is to be executed from the time the request is approved. An authorized user can set the execution-expiry to the ONTAP operation rule. If the user does not set the execution-expiry to the rule, then the execution-expiry from the global setting is applied.

**[-users-approved <text>,...] - Approvals**

This specifies the list of users that have approved the request.

**[-user-vetoed <text>] - User Vetoed**

This specifies the user who vetoed the request.

**[-vserver <vserver>] - Vserver**

This specifies the Vserver information to which the request is associated with.

**[-user-requested <text>] - User Requested**

This specifies the username who created the request.

**[-time-created <MM/DD/YYYY HH:MM:SS>] - Time Created**

This specifies the time at which the request is created.

**[-time-approved <MM/DD/YYYY HH:MM:SS>] - Time Approved**

This specifies the time at which the request state changed to approved.

**[-comment <text>] - Comment**

This specifies the comments that are associated with the request.

**[-users-permitted <text>,...] - Users Permitted**

This specifies the list of users that are permitted to perform the ONTAP operation for which the request is approved. If users-permitted is empty, then any user who, by default, has permission to

perform the ONTAP operation is allowed.

## Examples

The following example displays typical request information:

```
cluster1::> security multi-admin-verify request show-pending
Pending
  Index Operation                Query                State  Approvers Requestor
  -----
    1 volume delete              pending 3          admin
```

# security multi-admin-verify request show

Display requests

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `security multi-admin-verify request show` command displays information about multi-admin verification requests.

## Parameters

{ [-fields <fieldname>, ... ] }

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

{ [-instance ] }

If you specify the `-instance` parameter, the command displays detailed information about all fields.

**[-index <integer>] - Request Index**

This specifies the index of the request.

**[-operation <text>] - Operation**

This specifies the ONTAP operation for which the request is created.

**[-query <query>] - Query**

This identifies the object (or objects) upon which the user wants to apply the operation.

**[-state {pending|approved|vetoed|expired|executed}] - State**

This specifies the query information that is applied to the subset of objects of ONTAP operation

of the request.

### **[-required-approvers <integer>] - Required Approvers**

This specifies the number of distinct users that are required to approve the request. A user can set the required-approvers to the ONTAP operation rule. If a user does not set the required-approvers to the rule, then the required-approvers from the global setting is applied.

### **[-pending-approvers <integer>] - Pending Approvers**

This specifies the number of distinct users that are still required to approve the request for the request to be marked as approved.

### **[-approval-expiry {MM/DD/YYYY HH:MM:SS | {1..7}days | {1..168}hours | PnDTnHnMnS | PnW}] - Approval Expiry**

This specifies the expiry information within which an approve or veto action is to be taken by the approvers from the time the request is submitted. Any authorized user can set the approval-expiry to the ONTAP operation rule. If the user does not set the approval-expiry to the rule, then the approval-expiry from the global setting is applied.

### **[-execution-expiry {MM/DD/YYYY HH:MM:SS | {1..7}days | {1..168}hours | PnDTnHnMnS | PnW}] - Execution Expiry**

This specifies the expiry information within which an ONTAP operation is to be executed from the time the request is approved. An authorized user can set the execution-expiry to the ONTAP operation rule. If the user does not set the execution-expiry to the rule, then the execution-expiry from the global setting is applied.

### **[-users-approved <text>,...] - Approvals**

This specifies the list of users that have approved the request.

### **[-user-vetoed <text>] - User Vetoed**

This specifies the user who vetoed the request.

### **[-vserver <vserver>] - Vserver**

This specifies the Vserver information to which the request is associated with.

### **[-user-requested <text>] - User Requested**

This specifies the username who created the request.

### **[-time-created <MM/DD/YYYY HH:MM:SS>] - Time Created**

This specifies the time at which the request is created.

### **[-time-approved <MM/DD/YYYY HH:MM:SS>] - Time Approved**

This specifies the time at which the request state changed to approved.

### **[-comment <text>] - Comment**

This specifies the comments that are associated with the request.

### **[-users-permitted <text>,...] - Users Permitted**

This specifies the list of users that are permitted to perform the ONTAP operation for which the

request is approved. If `users-permitted` is empty, then any user who, by default, has permission to perform the ONTAP operation is allowed.

## Examples

The following example displays typical request information:

```
cluster1::> security multi-admin-verify request show
Pending
  Index Operation                Query                State  Approvers Requestor
-----
    1 volume delete                pending           3      admin
```

## security multi-admin-verify request veto

Veto a request

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `security multi-admin-verify request veto` command vetoes the specified request.

## Parameters

`-index <integer>` - Request Index

This allows the user to specify the index of the request to be vetoed.

## Examples

The following example vetoes the request with index 1:

```
cluster1::> security multi-admin-verify request veto -index 1
```

## security multi-admin-verify rule create

Create a rule

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `security multi-admin-verify rule create` command creates a rule for the specified ONTAP operation.

## Parameters

### `[-vserver <vserver>] - Vserver`

This specifies Vserver information for which the rule should be associated with. This is an optional parameter. This parameter defaults to a Cluster server and supports only Cluster servers.

### `-operation <text> - Operation`

This specifies the ONTAP operation information for the rule to be created.

### `[-auto-request-create {true|false}] - Automatic Request Creation`

This specifies rule information for the auto request create state. Auto request creation for the rule is enabled by default, by setting this value to true.

### `[-query <query>] - Query`

This specifies the query information which is applied to the subset of objects of ONTAP operation of the rule to be created. This is an optional parameter. If a query is not specified for the rule, the rule applies to all objects of the ONTAP operation.

### `[-required-approvers {<integer>|-}] - Required Number of Approvers`

This specifies the required number of approvers to approve the ONTAP execution request. This is an optional parameter. If `required-approvers` is not specified for the rule, the `required-approvers` from the global setting is applied to the ONTAP operation request. The `required-approvers` from the global setting can be viewed using the `security multi-admin-verify show` command. The minimum supported value is 1.

### `[-approval-groups <text>,...] - Approval Groups`

This specifies the list of users who can approve the ONTAP operation request. This is an optional parameter. If `approval-groups` is not specified for the rule, the `approval-groups` from the global setting is applied to the ONTAP operation request. The `approval-groups` from the global setting can be viewed using the `security multi-admin-verify show` command.

### `[-execution-expiry [<integer>h][<integer>m][<integer>s]>] - Execution Expiry`

This specifies the amount of time after a request has been approved by which the operation must be executed before the approved execution request expires. This is an optional parameter. If `execution-expiry` is not specified for the rule, the `execution-expiry` from the global setting is applied to the ONTAP execution request. The `execution-expiry` from the global setting can be viewed using the `security multi-admin-verify show` command. The default value is one hour (**1h**), the minimum supported value is one second (**1s**), and the maximum supported value is 14 days (**14d**).

### `[-approval-expiry [<integer>h][<integer>m][<integer>s]>] - Approval Expiry`

This specifies the amount of time after a new execution request is submitted by which approvers

have to approve or disapprove the request before the pending execution request expires. This is an optional parameter. If approval-expiry is not specified for the rule, the approval-expiry from the global setting is applied to the ONTAP execution request. The approval-expiry from the global setting can be viewed using the [security multi-admin-verify show](#) command. The default value is one hour (**1h**), the minimum supported value is one second (**1s**), and the maximum supported value is 14 days (**14d**).

## Examples

The following example creates a new rule for the ONTAP operation volume delete with 3 required approvers and is applicable to Vserver vs0 objects:

```
cluster1::> security multi-admin-verify rule create -operation "volume delete" -query "-vserver vs0" -required-approvers 3
```

## Related Links

- [security multi-admin-verify show](#)

# security multi-admin-verify rule delete

Delete a rule

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `security multi-admin-verify rule delete` command deletes the specified rule.

## Parameters

**-vserver <vserver> - Vserver**

This specifies the Vserver information to which the rule is associated with. This is an optional parameter. This parameter defaults to a Cluster server and supports only Cluster servers.

**-operation <text> - Operation**

This specifies the ONTAP operation whose associated rule is to be deleted.

## Examples

The following example deletes the rule for ONTAP operation volume delete and the default Vserver cluster1:

```
cluster1::> security multi-admin-verify rule delete -operation "volume delete"
```

# security multi-admin-verify rule modify

Modify a rule

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **security multi-admin-verify rule modify** command is used to modify the attributes of the rule.

## Parameters

### **-vserver <vserver> - Vserver**

This specifies Vserver information for which the rule should be associated with. This is an optional parameter. This parameter defaults to a Cluster server and supports only Cluster servers.

### **-operation <text> - Operation**

This specifies the ONTAP operation information for the rule to be created.

### **[-auto-request-create {true|false}] - Automatic Request Creation**

This specifies rule information for the auto request create state. Auto request creation for the rule is enabled by default, by setting this value to true.

### **[-query <query>] - Query**

This specifies the query information which is applied to the subset of objects of ONTAP operation of the rule to be created. This is an optional parameter. If a query is not specified for the rule, the rule applies to all objects of the ONTAP operation.

### **[-required-approvers {<integer>|-}] - Required Number of Approvers**

This specifies the required number of approvers to approve the ONTAP execution request. This is an optional parameter. If required-approvers is not specified for the rule, the required-approvers from the global setting is applied to the ONTAP operation request. The required-approvers from the global setting can be viewed using the [security multi-admin-verify show](#) command. The minimum supported value is 1.

### **[-approval-groups <text>,...] - Approval Groups**

This specifies the list of users who can approve the ONTAP operation request. This is an optional parameter. If approval-groups is not specified for the rule, the approval-groups from the global setting is applied to the ONTAP operation request. The approval-groups from the global setting can be viewed using the [security multi-admin-verify show](#) command.

**[-execution-expiry <[<integer>h][<integer>m][<integer>s]>] - Execution Expiry**

This specifies the amount of time after a request has been approved by which the operation must be executed before the approved execution request expires. This is an optional parameter. If execution-expiry is not specified for the rule, the execution-expiry from the global setting is applied to the ONTAP execution request. The execution-expiry from the global setting can be viewed using the [security multi-admin-verify show](#) command. The default value is one hour (**1h**), the minimum supported value is one second (**1s**), and the maximum supported value is 14 days (**14d**).

**[-approval-expiry <[<integer>h][<integer>m][<integer>s]>] - Approval Expiry**

This specifies the amount of time after a new execution request is submitted by which approvers have to approve or disapprove the request before the pending execution request expires. This is an optional parameter. If approval-expiry is not specified for the rule, the approval-expiry from the global setting is applied to the ONTAP execution request. The approval-expiry from the global setting can be viewed using the [security multi-admin-verify show](#) command. The default value is one hour (**1h**), the minimum supported value is one second (**1s**), and the maximum supported value is 14 days (**14d**).

## Examples

This command changes the approval groups:

```
cluster1::> security multi-admin-verify rule modify -operation "volume delete"
-approval-groups group1, group2
```

This command changes the required number of approvers:

```
cluster1::> security multi-admin-verify rule modify -operation "volume snapshot
delete" -required-approvers 3
```

This command changes the query:

```
cluster1::> security multi-admin-verify rule modify -operation "volume delete" -query
"-vserver vs1"
```

This command changes the execution expiry:

```
cluster1::> security multi-admin-verify rule modify -operation "volume delete"
-execution-expiry 14d
```

This command changes the approval expiry:

```
cluster1::> security multi-admin-verify rule modify -operation "volume delete"
```

```
-approval-expiry 48h
```

- [security multi-admin-verify show](#)

# security multi-admin-verify rule show

Display rules

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `security multi-admin-verify rule show` command displays information about multi admin verification rules.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

**[ -instance ] }**

If you specify the `-instance` parameter, the command displays detailed information about all fields.

**[ -vserver <vserver> ] - Vserver**

This specifies the Vserver information to which the rule is associated with. This is an optional parameter. This parameter defaults to a Cluster server and supports only Cluster servers.

**[ -operation <text> ] - Operation**

This specifies the ONTAP operation information for which the rule is created.

**[ -auto-request-create {true|false} ] - Automatic Request Creation**

This specifies the information of the auto request create state for the rule.

**[ -query <query> ] - Query**

This specifies the query information which is applied to the subset of objects of ONTAP operation of the rule.

**[ -required-approvers {<integer>|-} ] - Required Number of Approvers**

This specifies the number of approvers that are required to approve the ONTAP execution request.

**[-approval-groups <text>,...] - Approval Groups**

This specifies the list of approval groups that lists the users who can approve the ONTAP execution request.

**[-execution-expiry <[<integer>h][<integer>m][<integer>s]>] - Execution Expiry**

This specifies the amount of time that the authorized users have after a request is approved to execute the requested operation before the request expires.

**[-approval-expiry <[<integer>h][<integer>m][<integer>s]>] - Approval Expiry**

This is the amount of time that the approvers have after a new execution request is submitted to approve or disapprove the request before the request expires.

**[-time-created <MM/DD/YYYY HH:MM:SS>] - Time Created**

This specifies the time at which the rule is created.

**[-system-defined {true|false}] - Is System Defined**

Displays the value true if rule is defined by the system. Displays the value false if rule is defined by the user.

## Examples

The following example displays typical rule information:

```
cluster1::> security multi-admin-verify rule show
```

Vserver	Operation	Required Approvers	Approval Groups
cluster1	security login password	1	-
	Query: -multi-admin-approver true -different-user true		
	security multi-admin-verify approval-group create	1	-
	security multi-admin-verify approval-group delete	1	-
	security multi-admin-verify approval-group modify	1	-
	security multi-admin-verify approval-group replace	1	-
	security multi-admin-verify modify	1	-
	security multi-admin-verify rule create	1	-
	security multi-admin-verify rule delete	1	-
	security multi-admin-verify rule modify	1	-
	volume delete	3	-
	Query: -vserver vs0		

10 entries were displayed.

# security protocol modify

Modify application configuration options

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **security protocol modify** command modifies the existing cluster-wide configuration of RSH and Telnet. Enable RSH and Telnet in the cluster by setting the `enabled` field as **true**.

## Parameters

**-application <text> - application**

Selects the application. Supported values are **rsh** and **telnet**.

**[-enabled {true|false}] - enabled**

Enables or disables the corresponding application. The default value is **false**.

## Examples

The following command enables RSH in the cluster. The default setting for RSH is **false**:

```
cluster1::> security protocol modify -application rsh -enabled true
```

The following command enables Telnet in the cluster. The default setting for Telnet is **false**:

```
cluster1::> security protocol modify -application telnet -enabled true
```

# security protocol show

Show application configuration options

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **security protocol show** command displays the cluster-wide configuration of RSH and Telnet in the cluster in advanced privilege mode. RSH and Telnet are disabled by default. Use the [security protocol modify](#) command to change the RSH and Telnet configuration that the cluster supports.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[ [-instance ] ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-application <text>] - application**

Displays the insecure applications in the cluster.

**[-enabled {true|false}] - enabled**

Displays whether the application is enabled or disabled in the cluster.

## Examples

The following example shows the default security protocol configurations for a cluster:

```
cluster1::> security protocol show

Application      Enabled
-----
rsh              false
telnet          false
```

The following example shows the security protocol configuration after RSH and Telnet have been enabled:

```
cluster1::> security protocol show

Application      Enabled
-----
rsh              true
telnet          true
```

# security protocol ssh modify

Modify the SSH configuration

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `security protocol ssh modify` command modifies the existing cluster-wide configuration of SSH

## Parameters

### `[-per-source-limit <integer>] - Per-Source Limit`

Modifies the maximum number of SSH instances per source IP address on a per-node basis.

### `[-max-instances <integer>] - Maximum Number of Instances`

Modifies the maximum number of SSH instances that can be handled on a per-node basis.

### `[-connections-per-second <integer>] - Connections Per Second`

Modifies the maximum number of SSH connections per second on a per-node basis.

## Examples

The following example modifies cluster-wide SSH configuration:

```
cluster1::*> security protocol ssh modify -per-source-limit 30 -max-instances 60  
-connections-per-second 5
```

## security protocol ssh show

Show the SSH configuration

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The `security protocol ssh show` command displays the cluster-wide SSH configuration in advanced privilege mode. Use the `security protocol ssh modify` command to change the SSH configuration that the cluster supports.

## Examples

The following example displays cluster-wide SSH configuration:

```
cluster1::*> security protocol ssh show  
Per-Source Limit: 32  
Maximum Number of Instances: 64
```

Connections Per Second: 10

# security saml-sp create

Configure SAML service provider for authentication

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **security saml-sp create** command configures ONTAP with Security Assertion Markup Language (SAML) Service Provider (SP) for single sign-on authentication. This command does not enable SAML SP, it just configures it. Configuring and enabling SAML SP is a two-step process:

- Create a SAML SP configuration using **security saml-sp create** command.
- Enable SAML SP by using **security saml-sp modify -is-enabled true**

After the SAML SP configuration is created, it cannot be modified. It must be deleted and created again to change any settings.

This restarts the web server. Any HTTP/S connections that are active will be disrupted.

## Parameters

**-idp-uri {(ftp|http|https)://(hostname|IPv4 Address|['IPv6 Address'])...} - Identity Provider (IdP) Metadata Location**

This is the URI of the desired identity provider's (IdP) metadata.

**[-sp-host <Remote InetAddress>] - SAML Service Provider Host**

This specifies the SAML service provider host IP address.

**{ -cert-ca <text> - Server Certificate Issuing CA**

This specifies the service provider's certificate issuing CA.

**-cert-serial <text> - Server Certificate Serial Number**

This specifies the service provider's certificate's serial number.

**[[-cert-common-name <FQDN or Custom Common Name>] - Server Certificate Common Name }**

This specifies the service provider certificate's common name.

### **[`-verify-metadata-server {true|false}`] - Verify IdP Metadata Server Identity**

When the IdP metadata is downloaded, the identity of the server hosting the metadata is verified using transport layer security (TLS), validating the server's X.509 certificate against the list of certificate authorities (CAs) in Data ONTAP, and verifying that the host in the server certificate matches the host in the URI (the `idp-uri` field). This verification can be bypassed by setting this field to **false**. Bypassing the server verification is not recommended as the server can not be trusted that way, but will be necessary to use non-TLS URIs, e.g. with the "http" scheme, or when the server certificates are self-signed. If the server's certificate was signed by a CA that is not installed in Data ONTAP, the [security certificate install -type server-ca](#) command can be used to install it.

### **[`-foreground {true|false}`] - Foreground Process**

When this parameter is set to **false** the command runs in the background as a job. The default is **true**, which causes the command to return after the operation completes.

## Examples

The following example configures ONTAP with SAML SP IdP information:

```
cluster1::> security saml-sp create -idp-uri http://public-idp-uri -sp-host 1.1.1.1
[Job 9] Job succeeded.
cluster1::>
```

# security saml-sp delete

Delete SAML service provider for authentication

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `security saml-sp delete` command is used to remove the Security Access Markup Language (SAML) Service Provider (SP). Running this command frees resources used by the SP. SAML SP services will no longer be available after the SP is removed.

If the SAML SP is currently enabled, it is necessary to first use `security saml-sp modify -is-enabled false` prior to `security saml-sp delete`. The `security saml-sp modify -is-enabled false` command must be issued by a password authenticated console application user or from a SAML authenticated command interface.

This restarts the web server. Any HTTP/S connections that are active will be disrupted.

## Examples

The following example unconfigures SAML SP:

```
cluster1::> security saml-sp delete
cluster1::>
```

## Related Links

- [security saml-sp modify](#)

# security saml-sp modify

Modify SAML service provider authentication

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `security saml-sp modify` command modifies the Security Assertion Markup Language (SAML) Service Provider (SP) configuration for single sign-on authentication. This command is used to enable or disable an existing SAML SP, `security saml-sp modify-is-enabled`true or false`` respectively.

This command will check the validity of the current SAML SP configuration before enabling the SP. Also, it is necessary to use this command with the `-is-enabled`false` parameter prior to deleting an existing SAML SP configuration. SAML SP can only be disabled in this way by a password authenticated console application user or from a SAML authenticated command interface. The delete command must be used if the SAML configuration settings are to be changed, as only the ``is-enabled` parameter can be modified.

This may restart the web server. Any HTTP/S connections that are active may be disrupted.

## Parameters

`[-is-enabled {true|false}] - SAML Service Provider Enabled`

Use this parameter to enable or disable the SAML SP.

## Examples

The following example enables SAML SP:

```
cluster1::> security saml-sp modify -is-enabled true
cluster1::>
```

## security saml-sp repair

Repair a failed SAML SP configuration

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

The `security saml-sp repair` command attempts to repair a failed SAML SP configuration on a given node. The status of the individual nodes can be viewed using the [security saml-sp status show](#) command.

This restarts the web server. Any active HTTP/S requests to the web server will be disrupted.

### Parameters

`-node {<nodename>|local}` - **Node**

This identifies a single node that matches the input. The repair job will run on this node.

`[-foreground {true|false}]` - **Foreground Process**

When this parameter is set to **false** the command runs in the background as a job. The default is **true**, which causes the command to return after the operation completes.

### Examples

The following example repairs a failed SAML SP configuration:

```
cluster1:> security saml-sp repair -node node-2
Warning: This restarts the web server. Any active HTTP/S requests to the web
server will be disrupted
Do you want to continue? {y|n}: y
[Job 1321] Job succeeded.
cluster1:>
```

### Related Links

- [security saml-sp status show](#)

# security saml-sp show

Display SAML service provider for authentication

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **security saml-sp show** command displays the Security Assertion Markup Language (SAML) Service Provider (SP) configuration.

The **Identity Provider (IdP) URI** indicates the URI of the desired IdP's metadata.

The **Service Provider (SP) host** indicates the IP address containing SAML SP metadata.

The **Certificate Common Name** indicates the SAML SP certificate's common name.

The **Certificate Serial** indicates the SAML SP certificate's serial number.

## Examples

The following example displays the SAML SP configuration:

```
cluster1::> security saml-sp show
Identity Provider URI: https://www.my.idp.com
  Service Provider Host: 1.1.1.1
    Certificate Name: mycert
      Certificate Serial: 1234abcd
        Is SAML Enabled: false
```

# security saml-sp status show

Display SAML service provider configuration status

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

The **security saml-sp status show** command displays the SAML Service Provider (SP) status for all nodes in the cluster.

## Parameters

{ [-fields <fieldname>, ...]

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the

specified field or fields. You can use '-fields ?' to display the fields to specify.

### **[[-instance ]]**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

### **[-node {<nodename>|local}] - Node**

This identifies the node in the cluster.

### **[-status {not-configured|config-in-progress|config-failed|config-success}] - Update Status**

This identifies the SAML SP status on the specified node.

### **[-error-text <text>] - Error Text**

This identifies the error text associated with the latest saml SP update for this node.

### **[-is-enabled {true|false}] - SAML Service Provider Enabled**

When this parameter is set to **true** it indicates that the SAML SP is enabled on this node. Similarly, when this parameter is set to **false**, it indicates that the SAML SP is not enabled on this node.

## Examples

The following example displays the SAML SP status information for all nodes in the cluster.

```
cluster::security saml-sp status> show
Node                               SAML SP Status      Enabled
-----
cluster-node1                     not-configured      false
cluster-node2                     not-configured      false
2 entries were displayed.

cluster::*>
```

## security session kill-cli

Kill a CLI session

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **security session kill-cli** command is used to terminate CLI sessions. If the session being killed is actively processing a non-read command, the kill will wait until the command is complete before terminating the session. If the session being killed is actively processing a read (show) command, the kill will wait until the current row is returned before terminating the session.

## Parameters

### **-node {<nodename>|local} - Node**

Selects the sessions that match this parameter value. This identifies the node that is processing the session.

### **[-interface {cli|ontapi|rest}] - Interface**

Selects the sessions that match this parameter value. This identifies the interface (CLI, ONTAPI, or REST) that is processing the session.

### **[-start-time <MM/DD HH:MM:SS>] - Start Time**

Selects the sessions that match this parameter value. This identifies the start time of the current active session.

### **-session-id <integer> - Session ID**

Selects the sessions that match this parameter value. This number uniquely identifies a management session within a given node.

### **[-vserver <vserver>] - Vserver**

Selects the sessions that match this parameter value. This identifies the Vserver associated with this management session.

### **[-username <text>] - Username**

Selects the sessions that match this parameter value. This identifies the authenticated user associated with this management session.

### **[-application <text>] - Client Application**

Selects the sessions that match this parameter value. This identifies the calling application by name.

### **[-location <text>] - Client Location**

Selects the sessions that match this parameter value. This identifies the location of the calling client application. This is typically the IP address of the calling client, or "console" or "localhost" for console or localhost connections.

### **[-idle-seconds <integer>] - Idle Seconds**

Selects the sessions that match this parameter value. When a session is not actively executing a command request (the session is idle), this indicates the time (in seconds) since the last request completed.

### **[-state {pending|active|idle}] - Session State**

Selects the sessions that match this parameter value. This identifies the state (pending, active, or idle) of the session. The state is "pending" if it hit a session limit and the session is waiting for another session to end. The state is "idle" for CLI sessions that are waiting at the command prompt. The state is "active" if the session is actively working on a request.

**[-request <text>] - Active Command**

Selects the sessions that match this parameter value. This identifies the request (command) that is currently being handled by the session.

**Examples**

The following example illustrates killing a CLI session by specifying the node and the session id.

```
cluster1::> security session show -node node1
```

Node: node1	Interface: cli				Idle	
Start Time	Sess ID	Application	Location	Vserver	Username	Seconds
03/27 16:58:13	1358	console	console	cluster1	admin	-
Active Seconds: 0 Request: security session show						
03/27 16:58:17	1359	ssh	10.98.16.164	cluster1	admin	650

2 entries were displayed.

```
cluster1::>
```

```
cluster1::> security session kill-cli -node node1 -session-id 1359
1 entry was acted on.
```

```
cluster1::> security session show -node node1
```

Node: node1	Interface: cli				Idle	
Start Time	Sess ID	Application	Location	Vserver	Username	Seconds
03/27 16:58:13	1358	console	console	cluster1	admin	-
Active Seconds: 0 Request: security session show						

```
cluster1::>
```

The following example illustrates killing a CLI session by specifying the node and specifying a query on idle-seconds.

```
cluster1::> security session show -node node1
```

Node: node1	Interface: cli				Idle	
Start Time	Sess ID	Application	Location	Vserver	Username	Seconds
03/27 16:58:13	1358	console	console	cluster1	admin	-
Active Seconds: 0 Request: security session show						
03/27 17:13:36	1479	ssh	10.98.16.164	cluster1	admin	83

2 entries were displayed.

```
cluster1::> security session kill-cli -node node1 -session-id * -idle-seconds > 80
1 entry was acted on.
```

```
cluster1::> security session show
```

Node: node1	Interface: cli	Idle
Start Time	Sess ID Application Location	Vserver Username Seconds
03/27 16:58:13	1358 console console	cluster1 admin -
Active Seconds: 0 Request: security session show		

```
cluster1::>
```

## security session show

Show current CLI, ONTAPI, and REST sessions

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **security session show** command displays all active management sessions across the cluster.

### Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[ [-instance ] ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node**

Selects the sessions that match this parameter value. This identifies the node that is processing the session.

**[-interface {cli|ontapi|rest}] - Interface**

Selects the sessions that match this parameter value. This identifies the interface (CLI, ONTAPI, or REST) that is processing the session.

**[-start-time <MM/DD HH:MM:SS>] - Start Time**

Selects the sessions that match this parameter value. This identifies the start time of the current active session.

**[-session-id <integer>] - Session ID**

Selects the sessions that match this parameter value. This number uniquely identifies a management session within a given node.

**[-vserver <vserver>] - Vserver**

Selects the sessions that match this parameter value. This identifies the Vserver associated with this management session.

**[-username <text>] - Username**

Selects the sessions that match this parameter value. This identifies the authenticated user associated with this management session.

**[-application <text>] - Client Application**

Selects the sessions that match this parameter value. This identifies the calling application by name.

**[-location <text>] - Client Location**

Selects the sessions that match this parameter value. This identifies the location of the calling client application. This is typically the IP address of the calling client, or "console" or "localhost" for console or localhost connections.

**[-ipSPACE <IPspace>] - IPspace of Location**

Selects the sessions that match this parameter value. This identifies the IPspace of the client location.

**[-total <integer>] - Total Requests**

Selects the sessions that match this parameter value. This identifies the total number of requests that have been made thus far in the active session. The following commands are not counted: top, up, cd, rows, history, exit.

**[-failed <integer>] - Failed Requests**

Selects the sessions that match this parameter value. This identifies the number of requests that have failed for any reason (including if they were blocked by configured limits).

**[-max-time <integer>] - Maximum Time (ms)**

Selects the sessions that match this parameter value. This identifies the maximum amount of time (in milliseconds) that any request took for this session.

**[-last-time <integer>] - Last Time (ms)**

Selects the sessions that match this parameter value. This identifies the amount of time (in milliseconds) that the last request took for this session.

**[-total-seconds <integer>] - Total Seconds**

Selects the sessions that match this parameter value. This identifies the total time (in seconds) that has been taken by all completed requests for the current session; it does not include session idle time.

**[-state {pending|active|idle}] - Session State**

Selects the sessions that match this parameter value. This identifies the state (pending, active, or idle) of the session. The state is "pending" if it hit a session limit and the session is waiting for another session to end. The state is "idle" for CLI sessions that are waiting at the command

prompt. The state is "active" if the session is actively working on a request.

### **[-request <text>] - Request Input**

Selects the sessions that match this parameter value. This identifies the request (command) that is currently being handled by the session.

### **[-idle-seconds <integer>] - Idle Seconds**

Selects the sessions that match this parameter value. When a session is not actively executing a command request (the session is idle), this indicates the time (in seconds) since the last request completed.

### **[-active-seconds <integer>] - Active Seconds**

Selects the sessions that match this parameter value. When a session is actively executing a command request, this indicates the time (in seconds) since the current request started.

## Examples

The following example illustrates displaying all active sessions across the cluster. In this example, we see one active session on node **node2** from the **console** application. We also see three active sessions on node **node1**. One is from the **console** application and two are from the **ssh** application. Also one of the **ssh** sessions is from user **diag** and the other **ssh** session is from user **admin**.

```
cluster1::> security session show
```

Node: node1	Interface: cli				Idle
Start Time	Sess ID	Application	Location	Vserver Username	Seconds
03/27 16:58:13	1358	console	console	cluster1 admin	-
Active Seconds: 0 Request: security session show					
03/27 17:17:04	1514	ssh	10.98.16.164	cluster1 admin	139
03/27 17:17:29	1515	ssh	10.98.16.164	cluster1 diag	115

Node: node2	Interface: cli				Idle
Start Time	Sess ID	Application	Location	Vserver Username	Seconds
03/27 17:18:54	1509	console	console	cluster1 admin	23

4 entries were displayed.

```
cluster1::>
```

The following example illustrates displaying all active sessions that have been idle for longer than 500 seconds.

```
cluster1::> security session show -idle-seconds > 500
```

Node: node1	Interface: cli				Idle
Start Time	Sess ID	Application	Location	Vserver Username	Seconds

```

-----
03/27 17:17:04 1514    ssh          10.98.16.164    cluster1 admin    607
03/27 17:17:29 1515    ssh          10.98.16.164    cluster1 diag     583
2 entries were displayed.

cluster1::>

```

## security session limit create

Create default session limit

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

This command allows creation of a default management session limit that does not yet exist. The default limits can be overridden for specific values within each category by using advanced privilege level commands.

### Parameters

**-interface {cli|ontapi|rest} - Interface**

The interface (CLI, ONTAPI, or REST) to which the limit applies.

**-category {application|location|request|user|vserver} - Category**

The session type for this default limit. The following categories are supported: application, location, request, user, Vserver.

**-max-active-limit <integer> - Max-Active Limit**

The maximum number of concurrent sessions allowed for this interface and category.

### Examples

The following example illustrates creating a default limit for management sessions using the same application.

```

cluster1::> security session limit create -interface ontapi -category application -max
-active-limit 8

```

## security session limit delete

Delete default session limit

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command allows deletion of a default management session limit.

## Parameters

### **-interface {cli|ontapi|rest} - Interface**

The interface (CLI, ONTAPI, or REST) to which the limit applies.

### **-category {application|location|request|user|vserver} - Category**

The session type for this default limit. The following categories are supported: application, location, request, user, Vserver.

## Examples

The following example illustrates deleting all default limits for CLI management sessions.

```
cluster1::> security session limit delete -interface cli -category *  
3 entries were deleted.
```

# security session limit modify

Modify default session limit

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command allows modification of a default management session limit.

## Parameters

### **-interface {cli|ontapi|rest} - Interface**

The interface (CLI, ONTAPI, or REST) to which the limit applies.

### **-category {application|location|request|user|vserver} - Category**

The session type for this default limit. The following categories are supported: application, location, request, user, Vserver.

### **[-max-active-limit <integer>] - Max-Active Limit**

The maximum number of concurrent sessions allowed for this interface and category.

## Examples

The following example illustrates modifying the default limit for CLI management sessions from the same location.

```
cluster1::> security session limit modify -interface cli -category location -max
-active-limit 4
```

## security session limit show

Show default session limits

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command shows the default management session limits that have been configured for each interface and category.

## Parameters

**{[-fields <fieldname>,...]}**

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**{[-instance ]}**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-interface {cli|ontapi|rest}] - Interface**

Selects the sessions that match this parameter value. This identifies the interface (CLI, ONTAPI, or REST) to which the limit applies.

**[-category {application|location|request|user|vserver}] - Category**

Selects the sessions that match this parameter value. This identifies the category for the limit. The following categories are supported: application, location, request, user, and Vserver.

**[-max-active-limit <integer>] - Max-Active Limit**

Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

## Examples

The following example illustrates displaying the default limits for management sessions.

```
cluster1::> security session limit show
Interface Category    Max-Active
-----
cli      user      2
cli      vserver   4
ontapi   vserver   2
3 entries were displayed.
```

# security session limit application create

Create per-application session limit

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command allows creation of a per-application management session limit that does not yet exist.

## Parameters

**-interface {cli|ontapi|rest} - Interface**

The interface (CLI, ONTAPI, or REST) to which the limit applies.

**-application <text> - Application**

The specified application to which this limit applies. The limit with the application name **-default-** is the limit used for any application without a specific configured limit.

**-max-active-limit <integer> - Max-Active Limit**

The maximum number of concurrent sessions allowed for this interface and application.

## Examples

The following example illustrates creating a limit for management sessions from a custom application.

```
cluster1::*> security session limit application create -interface ontapi -application
"custom_app" -max-active-limit 8
```

# security session limit application delete

Delete per-application session limit

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command allows deletion of a per-application management session limit.

## Parameters

### **-interface {cli|ontapi|rest} - Interface**

The interface (CLI, ONTAPI, or REST) to which the limit applies.

### **-application <text> - Application**

The specified application to which this limit applies. The limit with the application name **-default-** is the limit used for any application without a specific configured limit.

## Examples

The following example illustrates deleting a limit for management sessions from a custom application.

```
cluster1::*> security session limit application delete -interface ontapi -application "custom_app"
```

# security session limit application modify

Modify per-application session limit

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command allows modification of a per-application management session limit.

## Parameters

### **-interface {cli|ontapi|rest} - Interface**

The interface (CLI, ONTAPI, or REST) to which the limit applies.

### **-application <text> - Application**

The specified application to which this limit applies. The limit with the application name **-default-** is the limit used for any application without a specific configured limit.

### **[-max-active-limit <integer>] - Max-Active Limit**

The maximum number of concurrent sessions allowed for this interface and application.

## Examples

The following example illustrates modifying management session limits for some custom applications.

```
cluster1::*> security session limit application modify -interface ontapi -application
custom* -max-active-limit 4
2 entries were modified.
```

## security session limit application show

Show per-application session limits

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command shows the per-application management session limits that have been configured for each interface and application.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[ -interface {cli|ontapi|rest} ] - Interface**

Selects the sessions that match this parameter value. This identifies the interface (CLI, ONTAPI, or REST) to which the limit applies.

**[ -application <text> ] - Application**

Selects the sessions that match this parameter value. This identifies the application for the limit. The limit with the application name **-default-** is the limit used for any application without a specific configured limit.

**[ -max-active-limit <integer> ] - Max-Active Limit**

Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

## Examples

The following example illustrates displaying the per-application limits for ONTAPI management sessions.

```
cluster1::*> security session limit application show -interface ontapi
Interface Application          Max-Active
-----
ontapi    -default-                    5
ontapi    custom_app                   10
2 entries were displayed.
```

## security session limit location create

Create per-location session limit

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

This command allows creation of a per-location management session limit that does not yet exist.

### Parameters

**-interface {cli|ontapi|rest} - Interface**

The interface (CLI, ONTAPI, or REST) to which the limit applies.

**-location <text> - Location**

The specified location to which this limit applies. The limit with the location name **-default-** (in the **Default** IPspace) is the limit used for any location (in any IPspace) without a specific configured limit.

**[-ipSPACE <IPspace>] - IPspace of Location**

This identifies the IPspace of the client location. If not specified, changes are made in the **Default** IPspace.

**-max-active-limit <integer> - Max-Active Limit**

The maximum number of concurrent sessions allowed for this interface and location.

## Examples

The following example illustrates creating a CLI limit for specific location.

```
cluster1::*> security session limit location create -interface cli -location
```

```
10.98.16.164 -max-active-limit 1
```

# security session limit location delete

Delete per-location session limit

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command allows deletion of a per-location management session limit.

## Parameters

**-interface {cli|ontapi|rest} - Interface**

The interface (CLI, ONTAPI, or REST) to which the limit applies.

**-location <text> - Location**

The specified location to which this limit applies. The limit with the location name **-default-** (in the **Default** IPspace) is the limit used for any location (in any IPspace) without a specific configured limit.

**[-ipSPACE <IPspace>] - IPspace of Location**

This identifies the IPspace of the client location. If not specified, changes are made in the **Default** IPspace.

## Examples

The following example illustrates deleting limits for management sessions from a specific set of locations.

```
cluster1::*> security session limit location delete -interface * -location 10.98.*
3 entries were deleted.
```

# security session limit location modify

Modify per-location session limit

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command allows modification of a per-location management session limit.

## Parameters

### -interface {cli|ontapi|rest} - Interface

The interface (CLI, ONTAPI, or REST) to which the limit applies.

### -location <text> - Location

The specified location to which this limit applies. The limit with the location name **-default-** (in the **Default** IPspace) is the limit used for any location (in any IPspace) without a specific configured limit.

### [-ipSpace <IPspace>] - IPspace of Location

This identifies the IPspace of the client location. If not specified, changes are made in the **Default** IPspace.

### [-max-active-limit <integer>] - Max-Active Limit

The maximum number of concurrent sessions allowed for this interface and location.

## Examples

The following example illustrates modifying management sessions limits for specific locations.

```
cluster1::*> security session limit location modify -interface * -location 10.98.*
-max-active-limit 2
3 entries were modified.
```

## security session limit location show

Show per-location session limits

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command shows the per-location management session limits that have been configured for each interface and location.

## Parameters

### {[-fields <fieldname>,...]}

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

### [-instance ]}

If you specify the **-instance** parameter, the command displays detailed information about all

fields.

### **[-interface {cli|ontapi|rest}] - Interface**

Selects the sessions that match this parameter value. This identifies the interface (CLI, ONTAPI, or REST) to which the limit applies.

### **[-location <text>] - Location**

Selects the sessions that match this parameter value. This identifies the location for the limit. The limit with the location name **-default-** (only in the **Default** IPspace) is the limit used for any location (in any IPspace) without a specific configured limit.

### **[-ipSpace <IPspace>] - IPspace of Location**

Selects the sessions that match this parameter value. This identifies the IPspace of the client location. The default IPspace is **Default**.

### **[-max-active-limit <integer>] - Max-Active Limit**

Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

## Examples

The following example illustrates displaying the per-location limits for management sessions.

```
cluster1::*> security session limit location show
Interface Location          IPspace      Max-Active
-----
cli      -default-          Default      16
cli      10.98.16.164      Default      0
ontapi   -default-          Default      6
ontapi   10.98.16.164      Default      0
4 entries were displayed.
```

# security session limit request create

Create per-request session limit

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command allows creation of a per-request management session limit that does not yet exist.

## Parameters

**-interface {cli|ontapi|rest} - Interface**

The interface (CLI, ONTAPI, or REST) to which the limit applies.

**-request <text> - Request Name**

The specified request to which this limit applies. The limit with the request name **-default-** is the limit used for any request without a specific configured limit.

**-max-active-limit <integer> - Max-Active Limit**

The maximum number of concurrent sessions allowed for this interface and request.

## Examples

The following example illustrates creating a limit for number of clients executing a specific API.

```
cluster1::*> security session limit request create -interface ontapi -request storage-disk-get-iter -max-active-limit 2
```

# security session limit request delete

Delete per-request session limit

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command allows deletion of a per-request management session limit.

## Parameters

**-interface {cli|ontapi|rest} - Interface**

The interface (CLI, ONTAPI, or REST) to which the limit applies.

**-request <text> - Request Name**

The specified request to which this limit applies. The limit with the request name **-default-** is the limit used for any request without a specific configured limit.

## Examples

The following example illustrates deleting custom limits for that were configured for the volume commands and APIs.

```
cluster1::*> security session limit request delete -interface * -request volume*
4 entries were deleted.
```

# security session limit request modify

Modify per-request session limit

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command allows modification of a per-request management session limit.

## Parameters

**-interface {cli|ontapi|rest} - Interface**

The interface (CLI, ONTAPI, or REST) to which the limit applies.

**-request <text> - Request Name**

The specified request to which this limit applies. The limit with the request name **-default-** is the limit used for any request without a specific configured limit.

**[-max-active-limit <integer>] - Max-Active Limit**

The maximum number of concurrent sessions allowed for this interface and request.

## Examples

The following example illustrates modifying the limit of the number of clients simultaneously executing a specific API.

```
cluster1::*> security session limit request modify -interface ontapi -request storage-disk-get-iter -max-active-limit 4
```

# security session limit request show

Show per-request session limits

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command shows the per-request management session limits that have been configured for each interface and request.

## Parameters

{ [-fields <fieldname>, ... ] }

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

{ [-instance ] }

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-interface {cli|ontapi|rest}] - Interface**

Selects the sessions that match this parameter value. This identifies the interface (CLI, ONTAPI, or REST) to which the limit applies.

**[-request <text>] - Request Name**

Selects the sessions that match this parameter value. This identifies the request (command or API) for the limit. The limit with the request name **-default-** is the limit used for any request without a specific configured limit.

**[-max-active-limit <integer>] - Max-Active Limit**

Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

## Examples

The following example illustrates displaying the per-request limits for management sessions.

```
cluster1::*> security session limit request show
Interface Request                               Max-Active
-----
cli      -default-                               10
ontapi   -default-                               5
ontapi   storage-disk-get-iter                   2
3 entries were displayed.
```

## security session limit user create

Create per-user session limit

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command allows creation of a per-user management session limit that does not yet exist.

## Parameters

### -interface {cli|ontapi|rest} - Interface

The interface (CLI, ONTAPI, or REST) to which the limit applies.

### -vserver <vserver> - Vserver

The specified Vserver to which this limit applies. The "Cluster" Vserver is used to limit Vservers that do not have a configured limit.

### -user <text> - User

The specified user to which this limit applies. The limit with the user name **-default-** is the limit used for any user without a specific configured limit.

### -max-active-limit <integer> - Max-Active Limit

The maximum number of concurrent sessions allowed for this interface, Vserver, and user.

## Examples

The following example illustrates creating a per-user limit override for ONTAPI requests for the **admin** user in the admin Vserver.

```
cluster1::*> security session limit user create -interface ontapi -vserver cluster1
-username admin -max-active-limit 16
```

## security session limit user delete

Delete per-user session limit

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command allows deletion of a per-user management session limit.

## Parameters

### -interface {cli|ontapi|rest} - Interface

The interface (CLI, ONTAPI, or REST) to which the limit applies.

### -vserver <vserver> - Vserver

The specified Vserver to which this limit applies. The "Cluster" Vserver is used to limit Vservers that do not have a configured limit.

**-user <text> - User**

The specified user to which this limit applies. The limit with the user name **-default-** is the limit used for any user without a specific configured limit.

## Examples

The following example illustrates deleting all user-specific limits for CLI management sessions.

```
cluster1::*> security session limit user delete -interface cli -user !"-default-"  
2 entries were deleted.
```

# security session limit user modify

Modify per-user session limit

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command allows modification of a per-user management session limit.

## Parameters

**-interface {cli|ontapi|rest} - Interface**

The interface (CLI, ONTAPI, or REST) to which the limit applies.

**-vserver <vserver> - Vserver**

The specified Vserver to which this limit applies. The "Cluster" Vserver is used to limit Vservers that do not have a configured limit.

**-user <text> - User**

The specified user to which this limit applies. The limit with the user name **-default-** is the limit used for any user without a specific configured limit.

**[-max-active-limit <integer>] - Max-Active Limit**

The maximum number of concurrent sessions allowed for this interface, Vserver, and user.

## Examples

The following example illustrates modifying the admin user's limit for CLI management sessions.

```
cluster1::*> security session limit user modify -interface cli -vserver cluster1  
-username admin -max-active-limit 30
```

# security session limit user show

Show per-user session limits

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command shows the per-user management session limits that have been configured for each interface, Vserver, and user.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[ -interface {cli|ontapi|rest} ] - Interface**

Selects the sessions that match this parameter value. This identifies the interface (CLI, ONTAPI, or REST) to which the limit applies.

**[ -vserver <vserver> ] - Vserver**

Selects the sessions that match this parameter value. This identifies the Vserver for the limit. The "Cluster" Vserver is used to limit Vservers that do not have a configured limit.

**[ -user <text> ] - User**

Selects the sessions that match this parameter value. This identifies the user for the limit. The limit with the user name **-default-** is the limit used for any user without a specific configured limit.

**[ -max-active-limit <integer> ] - Max-Active Limit**

Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

## Examples

The following example illustrates displaying the per-user limits for CLI management sessions. In this example, there is a default limit of 4 sessions for each user. That limit is expanded to 8 for the admin Vserver. That limit is further expanded to 20 for the **admin** user in the admin Vserver.

```
cluster1::*> security session limit user show -interface cli
Interface Vserver          User          Max-Active
```

```

-----
cli      Cluster      -default-      4
cli      cluster1     -default-      8
cli      cluster1     admin          20
3 entries were displayed.

```

## security session limit vserver create

Create per-vserver session limit

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

This command allows creation of a per-Vserver management session limit that does not yet exist.

### Parameters

**-interface {cli|ontapi|rest} - Interface**

The interface (CLI, ONTAPI, or REST) to which the limit applies.

**-vserver <vserver> - Vserver**

The specified Vserver to which this limit applies. The "Cluster" Vserver is used to limit Vservers that do not have a configured limit.

**-max-active-limit <integer> - Max-Active Limit**

The maximum number of concurrent sessions allowed for this interface and Vserver.

### Examples

The following example illustrates creating a per-Vserver limit override for ONTAPI requests on the admin Vserver.

```

cluster1::*> security session limit vserver create -interface ontapi -vserver cluster1
-max-active-limit 4

```

## security session limit vserver delete

Delete per-vserver session limit

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command allows deletion of a per-Vserver management session limit. The "Cluster" vserver is used when the specific Vserver doesn't have a configured limit.

## Parameters

### **-interface {cli|ontapi|rest} - Interface**

The interface (CLI, ONTAPI, or REST) to which the limit applies.

### **-vserver <vserver> - Vserver**

The specified Vserver to which this limit applies. The "Cluster" Vserver is used to limit Vservers that do not have a configured limit.

## Examples

The following example illustrates deleting all per-Vserver limits for management sessions except the default limit.

```
cluster1::*> security session limit vserver delete -interface * -vserver !Cluster
1 entries was deleted.
```

# security session limit vserver modify

Modify per-vserver session limit

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command allows modification of a per-Vserver management session limit.

## Parameters

### **-interface {cli|ontapi|rest} - Interface**

The interface (CLI, ONTAPI, or REST) to which the limit applies.

### **-vserver <vserver> - Vserver**

The specified Vserver to which this limit applies. The "Cluster" Vserver is used to limit Vservers that do not have a configured limit.

### **[-max-active-limit <integer>] - Max-Active Limit**

The maximum number of concurrent sessions allowed for this interface and Vserver.

## Examples

The following example illustrates modifying the admin Vserver's limit for CLI management sessions.

```
cluster1::*> security session limit vserver modify -interface cli -vserver cluster1
-max-active-limit 40
```

## security session limit vserver show

Show per-vserver session limits

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

## Description

This command shows the per-Vserver management session limits that have been configured for each interface and Vserver.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[ -interface {cli|ontapi|rest} ] - Interface**

Selects the sessions that match this parameter value. This identifies the interface (CLI, ONTAPI, or REST) to which the limit applies.

**[ -vserver <vserver> ] - Vserver**

Selects the sessions that match this parameter value. This identifies the Vserver for the limit. The "Cluster" Vserver is used to limit Vservers that do not have a configured limit.

**[ -max-active-limit <integer> ] - Max-Active Limit**

Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

## Examples

The following example illustrates displaying the per-Vserver limits for management sessions.

```
cluster1::*> security session limit vserver show
Interface Vserver          Max-Active
-----
cli      Cluster              4
ontapi   Cluster              2
ontapi   cluster1             16
3 entries were displayed.
```

## security session request-statistics show-by-application

Show session request statistics by application

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **security session request-statistics show-by-application** command shows historical statistics for management session activity, categorized by application name. CLI sessions connections will have an application name based on the connection method, i.e.: **ssh**, **telnet**, **rsh**, **console**, or **ngsh**. ONTAPI sessions will extract the application name from the ZAPI request. ONTAP looks for the application name in the following three locations, in the following order of precedence:

1. The "X-Dot-Client-App" HTTP header;
2. The "app-name" attribute of the "netapp" element, within the ZAPI XML request;
3. The "User-Agent" HTTP header.

### Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**{ [-instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node**

Selects the sessions that match this parameter value. This identifies the node that processed the session.

**[-interface {cli|ontapi|rest}] - Interface**

Selects the sessions that match this parameter value. This identifies the interface (CLI, ONTAPI, or

REST) that processed the session.

**[-application <text>] - Application**

Selects the sessions that match this parameter value. This identifies the calling application by name.

**[-total <integer>] - Total Requests**

Selects the sessions that match this parameter value. This identifies the total number of requests that have been made on a session. The following commands are not counted: top, up, cd, rows, history, exit.

**[-blocked <integer>] - Blocked Requests**

Selects the sessions that match this parameter value. This identifies the number of requests that were blocked due to configured limits.

**[-failed <integer>] - Failed Requests**

Selects the sessions that match this parameter value. This identifies the number of requests that failed for any reason (including if they were blocked by configured limits).

**[-max-time <integer>] - Maximum Time (ms)**

Selects the sessions that match this parameter value. This identifies the maximum amount of time (in milliseconds) that any request took.

**[-last-time <integer>] - Last Time (ms)**

Selects the sessions that match this parameter value. This identifies the amount of time (in milliseconds) that the last request took.

**[-active <integer>] - Number Active Now**

Selects the sessions that match this parameter value. This identifies the number of currently active sessions.

**[-max-active <integer>] - Max Number Active**

Selects the sessions that match this parameter value. This identifies the maximum number of concurrently active sessions.

**[-last-active-seconds <integer>] - Seconds Since Last Session Start**

Selects the sessions that match this parameter value. When a session is active, this indicates the time (in seconds) since the last session started.

**[-idle-seconds <integer>] - Idle Seconds**

Selects the sessions that match this parameter value. When no sessions are active, this indicates the time (in seconds) since the last session ended.

**[-total-seconds <integer>] - Total Seconds**

Selects the sessions that match this parameter value. This identifies the total time (in seconds) that have been taken by all completed requests; it does not include session idle time.

**[-average-time <integer>] - Average Time (ms)**

Selects the sessions that match this parameter value. This identifies the mean time spent processing requests.

**[-success-percent <percent>] - Success Percent**

Selects the sessions that match this parameter value. This identifies the percentage of successful requests.

**[-blocked-percent <percent>] - Blocked Percent**

Selects the sessions that match this parameter value. This identifies the percentage of requests that were blocked due to configured limits.

**[-failed-percent <percent>] - Failed Percent**

Selects the sessions that match this parameter value. This identifies the percentage of requests that failed for any reason (including if they were blocked by configured limits).

**[-max-active-limit <integer>] - Max-Active Limit**

Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

## Examples

The following example illustrates displaying historical statistics for all management session activity across the cluster, categorized by application name.

```
cluster1::> security session request-statistics show-by-application
```

Node: node1	Interface: cli					Idle	Total	
Application	Total	Now	Max	Pass	Fail	Seconds	Seconds	Avg (ms)
console	2126	0	6	95%	96	68	361	170
ssh	6	2	3	100%	0	-	794	132444

Node: node1	Interface: ontapi					Idle	Total	
Application	Total	Now	Max	Pass	Fail	Seconds	Seconds	Avg (ms)
api_test	2	0	1	100%	0	13	0	18

Node: node2	Interface: cli					Idle	Total	
Application	Total	Now	Max	Pass	Fail	Seconds	Seconds	Avg (ms)
console	2090	0	6	95%	96	90	655	313

4 entries were displayed.

```
cluster1::>
```

The following example illustrates displaying historical statistics for management session activity on a

specific node and for a specific application.

```
cluster1::> security session request-statistics show-by-application -node node1
-application api_test
```

Node: node1	Interface: ontapi					Idle	Total		
Application	Total	Now	Max	Pass	Fail	Seconds	Seconds	Avg (ms)	
api_test	2	0	1	100%	0	102	0	18	

```
cluster1::>
```

## security session request-statistics show-by-location

Show session request statistics by location

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The **security session request-statistics show-by-location** command shows historical statistics for management session activity, categorized by client location.

### Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**{ [-instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node**

Selects the sessions that match this parameter value. This identifies the node that processed the session.

**[-interface {cli|ontapi|rest}] - Interface**

Selects the sessions that match this parameter value. This identifies the interface (CLI, ONTAPI, or REST) that processed the session.

**[-location <text>] - Client Location**

Selects the sessions that match this parameter value. This identifies the location of the calling

client application. This is typically the IP address of the calling client, or "console" or "localhost" for console or localhost connections.

**[-ip-space <IPspace>] - IPspace of Location**

Selects the sessions that match this parameter value. This identifies the IPspace of the client location.

**[-total <integer>] - Total Requests**

Selects the sessions that match this parameter value. This identifies the total number of requests that have been made on a session. The following commands are not counted: top, up, cd, rows, history, exit.

**[-blocked <integer>] - Blocked Requests**

Selects the sessions that match this parameter value. This identifies the number of requests that were blocked due to configured limits.

**[-failed <integer>] - Failed Requests**

Selects the sessions that match this parameter value. This identifies the number of requests that failed for any reason (including if they were blocked by configured limits).

**[-max-time <integer>] - Maximum Time (ms)**

Selects the sessions that match this parameter value. This identifies the maximum amount of time (in milliseconds) that any request took.

**[-last-time <integer>] - Last Time (ms)**

Selects the sessions that match this parameter value. This identifies the amount of time (in milliseconds) that the last request took.

**[-active <integer>] - Number Active Now**

Selects the sessions that match this parameter value. This identifies the number of currently active sessions.

**[-max-active <integer>] - Max Number Active**

Selects the sessions that match this parameter value. This identifies the maximum number of concurrently active sessions.

**[-last-active-seconds <integer>] - Seconds Since Last Session Start**

Selects the sessions that match this parameter value. When a session is active, this indicates the time (in seconds) since the last session started.

**[-idle-seconds <integer>] - Idle Seconds**

Selects the sessions that match this parameter value. When no sessions are active, this indicates the time (in seconds) since the last session ended.

**[-total-seconds <integer>] - Total Seconds**

Selects the sessions that match this parameter value. This identifies the total time (in seconds) that have been taken by all completed requests; it does not include session idle time.

**[-average-time <integer>] - Average Time (ms)**

Selects the sessions that match this parameter value. This identifies the mean time spent processing requests.

**[-success-percent <percent>] - Success Percent**

Selects the sessions that match this parameter value. This identifies the percentage of successful requests.

**[-blocked-percent <percent>] - Blocked Percent**

Selects the sessions that match this parameter value. This identifies the percentage of requests that were blocked due to configured limits.

**[-failed-percent <percent>] - Failed Percent**

Selects the sessions that match this parameter value. This identifies the percentage of requests that failed for any reason (including if they were blocked by configured limits).

**[-max-active-limit <integer>] - Max-Active Limit**

Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

## Examples

The following example illustrates displaying historical statistics for all management session activity across the cluster, categorized by location.

```
cluster1::> security session request-statistics show-by-location
```

Node: node1		Interface: cli					Idle	Total	
Location	IPspace	Total	Now	Max	Pass	Fail	Seconds	Seconds	Avg (ms)
console	Default	21	1	1	100%	0	-	127	6063
localhost	Default	2523	0	5	95%	115	20	280	111

Node: node1		Interface: ontapi					Idle	Total	
Location	IPspace	Total	Now	Max	Pass	Fail	Seconds	Seconds	Avg (ms)
10.98.17.254	Default	2	0	1	100%	0	2419	0	18

Node: node2		Interface: cli					Idle	Total	
Location	IPspace	Total	Now	Max	Pass	Fail	Seconds	Seconds	Avg (ms)
console	Default	6	0	1	83%	1	2941	423	70557
localhost	Default	2502	0	5	95%	114	41	277	110

7 entries were displayed.

```
cluster1::>
```

The following example illustrates displaying historical statistics for management session activity on a specific node and for a specific location.

```
cluster1::> security session request-statistics show-by-location -node node2 -location localhost
```

Node: node2	Interface: cli					Idle	Total		
Location	IPspace	Total	Now	Max	Pass	Fail	Seconds	Seconds	Avg (ms)
localhost	Default	2524	0	5	95%	115	30	279	110

## security session request-statistics show-by-request

Show session request statistics by request name

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

### Description

The `security session request-statistics show-by-request` command shows historical statistics for management session activity, categorized by request (command or API name).

### Parameters

`{ [-fields <fieldname>, ... ] }`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

`{ [-instance ] }`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`[-node {<nodename>|local}] - Node`

Selects the sessions that match this parameter value. This identifies the node that processed the session.

`[-interface {cli|ontapi|rest}] - Interface`

Selects the sessions that match this parameter value. This identifies the interface (CLI, ONTAPI, or REST) that processed the session.

**[-request <text>] - Request Name**

Selects the sessions that match this parameter value. This identifies the command associated with these requests.

**[-total <integer>] - Total Requests**

Selects the sessions that match this parameter value. This identifies the total number of requests that have been made on a session. The following commands are not counted: top, up, cd, rows, history, exit.

**[-blocked <integer>] - Blocked Requests**

Selects the sessions that match this parameter value. This identifies the number of requests that were blocked due to configured limits.

**[-failed <integer>] - Failed Requests**

Selects the sessions that match this parameter value. This identifies the number of requests that failed for any reason (including if they were blocked by configured limits).

**[-max-time <integer>] - Maximum Time (ms)**

Selects the sessions that match this parameter value. This identifies the maximum amount of time (in milliseconds) that any request took.

**[-last-time <integer>] - Last Time (ms)**

Selects the sessions that match this parameter value. This identifies the amount of time (in milliseconds) that the last request took.

**[-active <integer>] - Number Active Now**

Selects the sessions that match this parameter value. This identifies the number of currently active requests.

**[-max-active <integer>] - Max Number Active**

Selects the sessions that match this parameter value. This identifies the maximum number of concurrently active requests.

**[-last-active-seconds <integer>] - Seconds Since Last Request Start**

Selects the sessions that match this parameter value. When requests are active, this indicates the time (in seconds) since the last request started.

**[-idle-seconds <integer>] - Idle Seconds**

Selects the sessions that match this parameter value. When no requests are active, this indicates the time (in seconds) since the last request ended.

**[-total-seconds <integer>] - Total Seconds**

Selects the sessions that match this parameter value. This identifies the total time (in seconds) that have been taken by all completed requests; it does not include session idle time.

**[-average-time <integer>] - Average Time (ms)**

Selects the sessions that match this parameter value. This identifies the mean time spent

processing requests.

#### **[-success-percent <percent>] - Success Percent**

Selects the sessions that match this parameter value. This identifies the percentage of successful requests.

#### **[-blocked-percent <percent>] - Blocked Percent**

Selects the sessions that match this parameter value. This identifies the percentage of requests that were blocked due to configured limits.

#### **[-failed-percent <percent>] - Failed Percent**

Selects the sessions that match this parameter value. This identifies the percentage of requests that failed for any reason (including if they were blocked by configured limits).

#### **[-max-active-limit <integer>] - Max-Active Limit**

Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

## Examples

The following example illustrates displaying historical statistics for all management session activity on a specific node, with a specific request query.

```
cluster1::> security session request-statistics show-by-request -node node1 -request network*
```

Node: node1	Interface: cli					Idle	Total	
Request Name	Total	Now	Max	Pass	Fail	Seconds	Seconds	Avg (ms)
network interface create	2	0	1	100%	0	2556	0	485
network interface modify	1	0	1	100%	0	2518	0	34
network interface show	8	0	1	100%	0	2152	12	1614
network route create	1	0	1	100%	0	2135	0	45
network route show	2	0	1	100%	0	2145	0	17

5 entries were displayed.

```

```

## security session request-statistics show-by-user

Show session request statistics by username

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The `security session request-statistics show-by-user` command shows historical statistics for management session activity, categorized by username. Entries for username 'autosupport' reflect commands that are executed by the AutoSupport OnDemand feature.

## Parameters

**{ [-fields <fieldname>,...]**

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

**[-instance ]}**

If you specify the `-instance` parameter, the command displays detailed information about all fields.

**[-node {<nodename>|local}] - Node**

Selects the sessions that match this parameter value. This identifies the node that processed the session.

**[-interface {cli|ontapi|rest}] - Interface**

Selects the sessions that match this parameter value. This identifies the interface (CLI, ONTAPI, or REST) that processed the session.

**[-vserver <vserver>] - Vserver**

Selects the sessions that match this parameter value. This identifies the Vserver associated with this management session.

**[-username <text>] - Username**

Selects the sessions that match this parameter value. This identifies the authenticated user associated with this management session.

**[-total <integer>] - Total Requests**

Selects the sessions that match this parameter value. This identifies the total number of requests that have been made on a session. The following commands are not counted: top, up, cd, rows, history, exit.

**[-blocked <integer>] - Blocked Requests**

Selects the sessions that match this parameter value. This identifies the number of requests that were blocked due to configured limits.

**[-failed <integer>] - Failed Requests**

Selects the sessions that match this parameter value. This identifies the number of requests that failed for any reason (including if they were blocked by configured limits).

**[-max-time <integer>] - Maximum Time (ms)**

Selects the sessions that match this parameter value. This identifies the maximum amount of time

(in milliseconds) that any request took.

**[-last-time <integer>] - Last Time (ms)**

Selects the sessions that match this parameter value. This identifies the amount of time (in milliseconds) that the last request took.

**[-active <integer>] - Number Active Now**

Selects the sessions that match this parameter value. This identifies the number of currently active sessions.

**[-max-active <integer>] - Max Number Active**

Selects the sessions that match this parameter value. This identifies the maximum number of concurrently active sessions.

**[-last-active-seconds <integer>] - Seconds Since Last Session Start**

Selects the sessions that match this parameter value. When a session is active, this indicates the time (in seconds) since the last session started.

**[-idle-seconds <integer>] - Idle Seconds**

Selects the sessions that match this parameter value. When no sessions are active, this indicates the time (in seconds) since the last session ended.

**[-total-seconds <integer>] - Total Seconds**

Selects the sessions that match this parameter value. This identifies the total time (in seconds) that have been taken by all completed requests; it does not include session idle time.

**[-average-time <integer>] - Average Time (ms)**

Selects the sessions that match this parameter value. This identifies the mean time spent processing requests.

**[-success-percent <percent>] - Success Percent**

Selects the sessions that match this parameter value. This identifies the percentage of successful requests.

**[-blocked-percent <percent>] - Blocked Percent**

Selects the sessions that match this parameter value. This identifies the percentage of requests that were blocked due to configured limits.

**[-failed-percent <percent>] - Failed Percent**

Selects the sessions that match this parameter value. This identifies the percentage of requests that failed for any reason (including if they were blocked by configured limits).

**[-max-active-limit <integer>] - Max-Active Limit**

Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

## Examples

The following example illustrates displaying historical statistics for all management session activity across the cluster, categorized by username.

```
cluster1::> security session request-statistics show-by-user
```

Node: node1		Interface: cli					Idle	Total	
Vserver	Username	Total	Now	Max	Pass	Fail	Seconds	Seconds	Avg (ms)
cluster1	admin	81	1	3	80%	16	-	1228	15171
	diag	1	0	1	100%	0	1982	1511	1511958
	autosupport	4	0	1	100%	0	-	0	17

Node: node1		Interface: ontapi					Idle	Total	
Vserver	Username	Total	Now	Max	Pass	Fail	Seconds	Seconds	Avg (ms)
cluster1	admin	2	0	1	100%	0	2585	0	18

Node: node2		Interface: cli					Idle	Total	
Vserver	Username	Total	Now	Max	Pass	Fail	Seconds	Seconds	Avg (ms)
cluster1	admin	6	1	1	83%	1	3106	423	70557

4 entries were displayed.

```
cluster1::>
```

The following example illustrates displaying historical statistics for management session activity on a specific node and for a specific username.

```
cluster1::> security session request-statistics show-by-user -node node1 -username diag
```

Node: node1		Interface: cli					Idle	Total	
Vserver	Username	Total	Now	Max	Pass	Fail	Seconds	Seconds	Avg (ms)
cluster1	diag	1	0	1	100%	0	-	1511	1511958

## security session request-statistics show-by-vserver

Show session request statistics by Vserver

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

The **security session request-statistics show-by-vserver** command shows historical statistics for management session activity, categorized by vservers.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[ -node {<nodename>|local} ] - Node**

Selects the sessions that match this parameter value. This identifies the node that processed the session.

**[ -interface {cli|ontapi|rest} ] - Interface**

Selects the sessions that match this parameter value. This identifies the interface (CLI, ONTAPI, or REST) that processed the session.

**[ -vserver <vserver> ] - Vserver**

Selects the sessions that match this parameter value. This identifies the Vserver associated with this management session.

**[ -total <integer> ] - Total Requests**

Selects the sessions that match this parameter value. This identifies the total number of requests that have been made on a session. The following commands are not counted: top, up, cd, rows, history, exit.

**[ -blocked <integer> ] - Blocked Requests**

Selects the sessions that match this parameter value. This identifies the number of requests that were blocked due to configured limits.

**[ -failed <integer> ] - Failed Requests**

Selects the sessions that match this parameter value. This identifies the number of requests that failed for any reason (including if they were blocked by configured limits).

**[ -max-time <integer> ] - Maximum Time (ms)**

Selects the sessions that match this parameter value. This identifies the maximum amount of time (in milliseconds) that any request took.

**[ -last-time <integer> ] - Last Time (ms)**

Selects the sessions that match this parameter value. This identifies the amount of time (in milliseconds) that the last request took.

**[-active <integer>] - Number Active Now**

Selects the sessions that match this parameter value. This identifies the number of currently active sessions.

**[-max-active <integer>] - Max Number Active**

Selects the sessions that match this parameter value. This identifies the maximum number of concurrently active sessions.

**[-last-active-seconds <integer>] - Seconds Since Last Session Start**

Selects the sessions that match this parameter value. When a session is active, this indicates the time (in seconds) since the last session started.

**[-idle-seconds <integer>] - Idle Seconds**

Selects the sessions that match this parameter value. When no sessions are active, this indicates the time (in seconds) since the last session ended.

**[-total-seconds <integer>] - Total Seconds**

Selects the sessions that match this parameter value. This identifies the total time (in seconds) that have been taken by all completed requests; it does not include session idle time.

**[-average-time <integer>] - Average Time (ms)**

Selects the sessions that match this parameter value. This identifies the mean time spent processing requests.

**[-success-percent <percent>] - Success Percent**

Selects the sessions that match this parameter value. This identifies the percentage of successful requests.

**[-blocked-percent <percent>] - Blocked Percent**

Selects the sessions that match this parameter value. This identifies the percentage of requests that were blocked due to configured limits.

**[-failed-percent <percent>] - Failed Percent**

Selects the sessions that match this parameter value. This identifies the percentage of requests that failed for any reason (including if they were blocked by configured limits).

**[-max-active-limit <integer>] - Max-Active Limit**

Selects the sessions that match this parameter value. This identifies the configured limit that is used to throttle or reject requests.

## Examples

The following example illustrates displaying historical statistics for all management session activity across the cluster, categorized by Vserver.

```
cluster1::> security session request-statistics show-by-vserver
```

security ssh add

```

Node: node1          Interface: cli          Idle   Total

## security ssh add

Add SSH configuration options

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The ``security ssh add`` command adds additional SSH key exchange algorithms or ciphers or MAC

algorithms to the existing configurations of the cluster or a Vserver. The added algorithms or ciphers or MAC algorithms are enabled on the cluster or Vserver. If you change the cluster configuration settings, it is used as the default for all newly created Vservers. The existing SSH key exchange algorithms, ciphers, and MAC algorithms remain unchanged in the configuration. If the SSH key exchange algorithms or ciphers or MAC algorithms are already enabled in the current configuration, the command will not fail. Data ONTAP supports the **diffie-hellman-group-exchange-sha256** key exchange algorithm for SHA-2. Data ONTAP also supports the **diffie-hellman-group-exchange-sha1**, **diffie-hellman-group14-sha1**, and **diffie-hellman-group1-sha1** SSH key exchange algorithms for SHA-1. The SHA-2 key exchange algorithm is more secure than the SHA-1 key exchange algorithms. Data ONTAP also supports **ecdh-sha2-nistp256**, **ecdh-sha2-nistp384**, **ecdh-sha2-nistp521**, and **curve25519-sha256**. Data ONTAP also supports the AES and 3DES symmetric encryptions (also known as ciphers) of the following types: **aes256-ctr**, **aes192-ctr**, **aes128-ctr**, **aes256-cbc**, **aes192-cbc**, **aes128-cbc**, **aes128-gcm**, **aes256-gcm**, and **3des-cbc**. Data ONTAP supports MAC algorithms of the following types: **hmac-sha1**, **hmac-sha1-96**, **hmac-md5**, **hmac-md5-96**, **umac-64**, **umac-128**, **hmac-sha2-256**, **hmac-sha2-512**, **hmac-sha1-etm**, **hmac-sha1-96-etm**, **hmac-sha2-256-etm**, **hmac-sha2-512-etm**, **hmac-md5-etm**, **hmac-md5-96-etm**, **umac-64-etm**, and **umac-128-etm**.

## Parameters

**-vserver <Vserver Name> - Vserver**

Identifies the Vserver to which you want to add additional SSH key exchange algorithms or ciphers.

**[-key-exchange-algorithms <algorithm name>,...] - List of SSH Key Exchange Algorithms to Add**

Adds the specified SSH key exchange algorithm or algorithms to the Vserver.

**[-ciphers <cipher name>,...] - List of SSH Ciphers to Add**

Adds the specified cipher or ciphers to the Vserver.

**[-mac-algorithms <MAC name>,...] - List of SSH MAC Algorithms to Add**

Adds the specified MAC algorithm or algorithms to the Vserver.

## Examples

The following command adds the **diffie-hellman-group-exchange-sha256** and **diffie-hellman-group-exchange-sha1** key exchange algorithms for the cluster1 Vserver. It also adds the **aes256-cbc** and **aes192-cbc** ciphers and the **hmac-sha1** and **hmac-sha2-256** MAC algorithms to the cluster1 Vserver.

```
cluster1::> security ssh add -vserver cluster1 -key-exchange-algorithms diffie-hellman-group-exchange-sha256,diffie-hellman-group-exchange-sha1 -ciphers aes256-cbc,aes192-cbc -mac-algorithms hmac-sha1,hmac-sha2-256
```

## security ssh modify

Modify SSH configuration options

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `security ssh modify` command replaces the existing configurations of the SSH key exchange algorithms or ciphers or MAC algorithms for the cluster or a Vserver with the configuration settings you specify. If you modify the cluster configuration settings, it will be used as the default for all newly created Vservers. Data ONTAP supports the **diffie-hellman-group-exchange-sha256** key exchange algorithm for SHA-2. Data ONTAP also supports the **diffie-hellman-group-exchange-sha1**, **diffie-hellman-group14-sha1**, and **diffie-hellman-group1-sha1** SSH key exchange algorithms for SHA-1. The SHA-2 key exchange algorithm is more secure than the SHA-1 key exchange algorithms. Data ONTAP also supports the AES and 3DES symmetric encryptions (also known as ciphers) of the following types: **aes256-ctr**, **aes192-ctr**, **aes128-ctr**, **aes256-cbc**, **aes192-cbc**, **aes128-cbc**, **aes128-gcm**, **aes256-gcm**, and **3des-cbc**. Data ONTAP supports MAC algorithms of the following types: **hmac-sha1**, **hmac-sha1-96**, **hmac-md5**, **hmac-md5-96**, **umac-64**, **umac-64**, **umac-128**, **hmac-sha2-256**, **hmac-sha2-512**, **hmac-sha1-etm**, **hmac-sha1-96-etm**, **hmac-sha2-256-etm**, **hmac-sha2-512-etm**, **hmac-md5-etm**, **hmac-md5-96-etm**, **umac-64-etm**, and **umac-128-etm**.

## Parameters

**-vserver <Vserver Name> - Vserver**

Identifies the Vserver for which you want to replace the existing SSH key exchange algorithm and cipher configurations.

**[-key-exchange-algorithms <algorithm name>,...] - Key Exchange Algorithms**

Enables the specified SSH key exchange algorithm or algorithms for the Vserver. This parameter also replaces all existing SSH key exchange algorithms with the specified settings.

**[-ciphers <cipher name>,...] - Ciphers**

Enables the specified cipher or ciphers for the Vserver. This parameter also replaces all existing ciphers with the specified settings.

**[-mac-algorithms <MAC name>,...] - MAC Algorithms**

Enables the specified MAC algorithm or algorithms for the Vserver. This parameter also replaces all existing MAC algorithms with the specified settings.

**[-max-authentication-retry-count <integer>] - Max Authentication Retry Count**

Modifies the maximum number of authentication retry count for the Vserver.

## Examples

The following command enables the **diffie-hellman-group-exchange-sha256** and **diffie-hellman-group14-sha1** key exchange algorithms for the cluster1 Vserver. It also enables the **aes256-ctr**, **aes192-ctr** and **aes128-ctr** ciphers, **hmac-sha1** and **hmac-sha2-256** MAC algorithms for the cluster1 Vserver. It also modifies the maximum authentication retry count to 3 for the cluster1 Vserver:

```
cluster1::> security ssh modify -vserver cluster1 -key-exchange-algorithms diffie-  
hellman-group-exchange-sha256,diffie-hellman-group14-sha1 -ciphers aes256-ctr,aes192-  
ctr,aes128-ctr -mac-algorithms hmac-sha1,hmac-sha2-256 -max-authentication-retry-count  
3
```

## security ssh remove

### Remove SSH configuration options

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `security ssh remove` command removes the specified SSH key exchange algorithms or ciphers from the existing configurations of the cluster or a Vserver. The removed algorithms or ciphers are disabled on the cluster or Vserver. If you changed the cluster configuration settings, it will be used as the default for all newly created Vservers. If the SSH key exchange algorithms or ciphers that you specify with this command are not currently enabled, the command does not fail. Data ONTAP supports the **diffie-hellman-group-exchange-sha256** key exchange algorithm for SHA-2. Data ONTAP also supports the **diffie-hellman-group-exchange-sha1**, **diffie-hellman-group14-sha1**, and **diffie-hellman-group1-sha1** SSH key exchange algorithms for SHA-1. The SHA-2 key exchange algorithm is more secure than the SHA-1 key exchange algorithms. Data ONTAP also supports **ecdh-sha2-nistp256**, **ecdh-sha2-nistp384**, **ecdh-sha2-nistp521**, and **curve25519-sha256**. Data ONTAP also supports the AES and 3DES symmetric encryption (also known as ciphers) of the following types: **aes256-ctr**, **aes192-ctr**, **aes128-ctr**, **aes256-cbc**, **aes192-cbc**, **aes128-cbc**, **aes128-gcm**, **aes256-gcm** and **3des-cbc**. Data ONTAP supports MAC algorithms of the following types: **hmac-sha1**, **hmac-sha1-96**, **hmac-md5**, **hmac-md5-96**, **umac-64**, **umac-64**, **umac-128**, **hmac-sha2-256**, **hmac-sha2-512**, **hmac-sha1-etm**, **hmac-sha1-96-etm**, **hmac-sha2-256-etm**, **hmac-sha2-512-etm**, **hmac-md5-etm**, **hmac-md5-96-etm**, **umac-64-etm**, and **umac-128-etm**.

## Parameters

**-vserver <Vserver Name> - Vserver**

Identifies the Vserver from which you want to remove the SSH key exchange algorithms or ciphers.

**[-key-exchange-algorithms <algorithm name>,...] - List of SSH Key Exchange Algorithms to Remove**

Removes the specified key exchange algorithm or algorithms from the Vserver.

**[-ciphers <cipher name>,...] - List of SSH Ciphers to Remove**

Removes the specified cipher or ciphers from the Vserver.

**[-mac-algorithms <MAC name>,...] - List of SSH MAC algorithms to Remove**

Removes the specified MAC algorithm or algorithms from the Vserver.

## Examples

The following command removes the **diffie-hellman-group1-sha1** and **diffie-hellman-group-exchange-sha1** key exchange algorithms from the cluster1 Vserver. It also removes the **aes128-cbc** and **3des-cbc** ciphers and the **hmac-sha1-96** and **hmac-sha2-256** MAC algorithms from the cluster1 Vserver.

```
cluster1::> security ssh remove -vserver cluster1 -key-exchange-algorithms diffie-hellman-group1-sha1,diffie-hellman-group-exchange-sha1 -ciphers aes128-cbc,3des-cbc -mac-algorithms hmac-sha1-96,hmac-sha2-256
```

## security ssh show

Display SSH configuration options

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `security ssh show` command displays the configurations of the SSH key exchange algorithms, ciphers, MAC algorithms and maximum authentication retry count for the cluster and Vservers. The SSH protocol uses a Diffie-Hellman based key exchange method to establish a shared secret key during the SSH negotiation phrase. The key exchange method specifies how one-time session keys are generated for encryption and authentication and how the server authentication takes place. Data ONTAP supports the `diffie-hellman-group-exchange-sha256` key exchange algorithm for SHA-2. Data ONTAP also supports the `diffie-hellman-group-exchange-sha1`, `diffie-hellman-group14-sha1`, and `diffie-hellman-group1-sha1` key exchange algorithms for SHA-1. Data ONTAP also supports `ecdh-sha2-nistp256`, `ecdh-sha2-nistp384`, `ecdh-sha2-nistp521`, and `curve25519-sha256`. Data ONTAP also supports the AES and 3DES symmetric encryptions (also known as ciphers) of the following types: `aes256-ctr`, `aes192-ctr`, `aes128-ctr`, `aes256-cbc`, `aes192-cbc`, `aes128-cbc`, `aes128-gcm`, `aes256-gcm` and `3des-cbc`. Data ONTAP supports MAC algorithms of the following types: `hmac-sha1`, `hmac-sha1-96`, `hmac-md5`, `hmac-md5-96`, `umac-64`, `umac-128`, `hmac-sha2-256`, `hmac-sha2-512`, `hmac-sha1-etm`, `hmac-sha1-96-etm`, `hmac-sha2-256-etm`, `hmac-sha2-512-etm`, `hmac-md5-etm`, `hmac-md5-96-etm`, `umac-64-etm`, and `umac-128-etm`.

## Parameters

`{[-fields <fieldname>,...]}`

If you specify the `-fields <fieldname>`, ... parameter, the command output also includes the specified field or fields. You can use `-fields ?` to display the fields to specify.

**[`-instance` ]}**

If you specify the `-instance` parameter, the command displays detailed information about all fields.

**[`-vserver <Vserver Name>`] - Vserver**

Identifies the Vserver for which you want to display the SSH key exchange algorithm, cipher, and MAC algorithm configurations.

**[`-key-exchange-algorithms <algorithm name>,...`] - Key Exchange Algorithms**

Displays the Vserver or Vservers that have the specified key exchange algorithms enabled.

**[`-ciphers <cipher name>,...`] - Ciphers**

Displays the Vserver or Vservers that have the specified ciphers enabled.

**[`-mac-algorithms <MAC name>,...`] - MAC Algorithms**

Displays the Vserver or Vservers that have the specified MAC algorithm or algorithms.

**[`-max-authentication-retry-count <integer>`] - Max Authentication Retry Count**

Displays Vservers with a matching maximum authentication retry count value.

## Examples

The following command displays the enabled SSH key exchange algorithms, ciphers, MAC algorithms and maximum number of authentication retry count for the cluster and all Vservers. The cluster settings are used as the default for all newly created Vservers:

```
cluster-1::> security ssh show
```

Vserver	Ciphers	Key Exchange Algorithms	MAC Algorithms	Max Authentication Retry Count
cluster-1	3des-cbc	diffie-hellman-group-exchange-sha256	hmac-sha1	4
vs1	aes256-ctr, aes192-ctr, aes128-ctr, aes256-cbc, aes192-cbc, aes128-cbc, 3des-cbc,	diffie-hellman-group-exchange-sha256, diffie-hellman-group-exchange-sha1, diffie-hellman-group14-	hmac-sha1, hmac-sha1-96, hmac-sha2-256, hmac-sha2-512, hmac-sha1-etm, hmac-sha1-96-etm, hmac-sha2-256-etm, hmac-sha2-512-etm, hmac-md5, hmac-md5-96, umac-64,	6

```

aes128-    sha1,          umac-128,
gcm,      ecdh-sha2-      hmac-md5-etm,
aes256-gcm nistp256,      hmac-md5-96-
           ecdh-sha2-      etm,
           nistp384,      umac-64-etm,
           ecdh-sha2-      umac-128-etm
           nistp521,
           curve25519-
           sha256

```

2 entries were displayed.

## security ssl modify

Modify the SSL configuration for HTTP servers

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

### Description

This command modifies the configuration of encrypted HTTP (SSL) for Vservers in the cluster. Depending on the requirements of the individual node's or cluster's web services (displayed by the [vserver services web show](#) command), this encryption might or might not be used. If the Vserver does not have a certificate associated with it, SSL will not be available.

### Parameters

**-vserver <Vserver Name> - Vserver**

Identifies a Vserver for hosting SSL-encrypted web services.

**[-ca <text>] - Server Certificate Issuing CA**

Identifies a Certificate Authority (CA) of a certificate to be associated with the instance of a given Vserver. If this parameter, along with serial, is omitted during modification, a self-signed SSL certificate can be optionally generated for that Vserver.

**[-serial <text>] - Server Certificate Serial Number**

Identifies a serial number of a certificate to be associated with the instance of a given Vserver. If this parameter, along with ca, is omitted during modification, a self-signed SSL certificate can be optionally generated for that Vserver.

**[-common-name <FQDN or Custom Common Name>] - Server Certificate Common Name**

Identifies the common name (CN) of a certificate to be associated with the instance of a given Vserver. This parameter becomes optional if serial and ca are specified. You can use the [security certificate create](#) and [security certificate install](#) commands to add new certificates to Vservers.

The use of self-signed SSL certificates exposes users to man-in-the-middle

security attacks. Where possible, obtain a certificate that is signed by a reputable certificate authority (CA) and use the [security\\_certificate\\_install](#) command to configure it before enabling SSL on a Vserver.

#### **[-server-enabled {true|false}] - SSL Server Authentication Enabled**

Defines the working condition of SSL server authentication in an instance of the Vserver. Any Vserver with a valid certificate of type server is server-enabled.

#### **[-client-enabled {true|false}] - SSL Client Authentication Enabled**

Defines the working condition of SSL client authentication in an instance of the Vserver. Any Vserver with a valid certificate of type client-ca is client-enabled. It can only be enabled if server-enabled is true.

#### **[-ocsp-enabled {true|false}] - Online Certificate Status Protocol Validation Enabled**

This parameter enables OCSP validation of the client certificate chain. When this parameter is enabled, certificates in the certificate chain of the client will be validated against an OCSP responder after normal verification (including CRL checks) has occurred. The OCSP responder used for validation process is either extracted from the certificate itself, or it is derived by configuration.

#### **[-ocsp-default-responder <text>] - URI of the Default Responder for OCSP Validation**

This parameter sets the default OCSP responder to use. If this parameter is not enabled, the URI given will be used only if no responder URI is specified in the certificate that are being verified.

#### **[-ocsp-override-responder {true|false}] - Force the Use of the Default Responder URI for OCSP Validation**

This parameter forces the configured default OCSP responder to be used during OCSP certificate validation, even if the certificate that is being validated references an OCSP responder.

#### **[-ocsp-responder-timeout <[<integer>h][<integer>m][<integer>s]>] - Timeout for OCSP Queries**

Use this parameter to specify the timeout in seconds for OSCP responders. Specify zero for the minimum possible timeout. The default value is 10 seconds.

#### **[-ocsp-max-response-age <unsigned32\_or\_unlimited>] - Maximum Allowable Age for OCSP Responses (secs)**

This parameter sets the maximum allowable age (freshness) in seconds for the OCSP responses. The default value for this parameter is unlimited, which does not enforce a maximum age and the OCSP responses are considered valid as long as their expiration date field is in the future.

#### **[-ocsp-max-response-time-skew <[<integer>h][<integer>m][<integer>s]>] - Maximum Allowable Time Skew for OCSP Response Validation**

This parameter sets the maximum allowable time difference for OCSP responses (when validating their ThisUpdate and NextUpdate fields).

#### **[-ocsp-use-request-nonce {true|false}] - Use a NONCE within OCSP Queries**

This parameter determines whether the queries to the OCSP responders should contain a NONCE or not. By default, a query NONCE is always used and checked against the OCSP response. When

the responder does not use NONCEs, this parameter should be disabled.

A NONCE is a unique identifier included in each OCSP request or OCSP response to prevent a replay attack.

## Examples

The following example enables SSL server authentication for a Vserver named vs0 with a certificate that has ca as www.example.com and serial as 4F4EB629.

```
cluster1::> security ssl modify -vserver vs0 -ca www.example.com -serial 4F4EB629
-server-enabled true
```

The following example disables SSL server authentication for a Vserver name vs0.

```
cluster1::> security ssl modify -vserver vs0 -server-enabled false
```

The following example enables SSL client authentication for a Vserver named vs0.

```
cluster1::> security ssl modify -vserver vs0 -client-enabled true
```

The following example disables SSL client authentication for a Vserver named vs0.

```
cluster1::> security ssl modify -vserver vs0 -client-enabled false
```

# security ssl show

Display the SSL configuration for HTTP servers

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

This command displays the configuration of encrypted HTTP (SSL) for Vservers in the cluster. Depending on the requirements of the individual node's or cluster's web services (displayed by the

`vserver services web show` command), this encryption might or might not be used. If the Vserver does not have a certificate associated with it, SSL will not be available.

## Parameters

### **{ [-fields <fieldname>, ... ] }**

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

### **[ -ocsp ]**

If you specify the `-ocsp` parameter, the command displays the Online Certificate Status Protocol configuration.

### **[ -instance ] }**

If you specify the `-instance` parameter, the command displays detailed information about all fields.

### **[ -vserver <Vserver Name> ] - Vserver**

Identifies a Vserver for hosting SSL-encrypted web services.

### **[ -ca <text> ] - Server Certificate Issuing CA**

Filters the display of SSL configuration by specifying the Certificate Authority (CA) that issued the server certificate.

### **[ -serial <text> ] - Server Certificate Serial Number**

Filters the display of SSL configuration by specifying the serial number of a server certificate.

### **[ -common-name <FQDN or Custom Common Name> ] - Server Certificate Common Name**

Filters the display of SSL configuration by specifying the common name for the server certificate.

### **[ -server-enabled { true|false } ] - SSL Server Authentication Enabled**

Filters the display of SSL configuration according to whether the SSL server authentication is enabled or disabled. Vservers have self-signed certificates automatically generated during their creation. These Vserver self-signed certificates are server-enabled by default.

### **[ -client-enabled { true|false } ] - SSL Client Authentication Enabled**

Filters the display of SSL configuration according to whether the SSL client authentication is enabled or disabled. You can enable client authentication only when server authentication is enabled.

### **[ -ocsp-enabled { true|false } ] - Online Certificate Status Protocol Validation Enabled**

Filters the display of SSL configuration when the Online Certificate Status Protocol validation is enabled.

### **[ -ocsp-default-responder <text> ] - URI of the Default Responder for OCSP Validation**

Filters the display of SSL configuration according to the URI of the default responder for OCSP validation.

### **[-ocsp-override-responder {true|false}] - Force the Use of the Default Responder URI for OCSP Validation**

Filters the display of SSL configuration, which forces the use of the default responder URI for OCSP validation.

### **[-ocsp-responder-timeout <[<integer>h][<integer>m][<integer>s]>] - Timeout for OCSP Queries**

Filters the display of SSL configuration according to the timeout for queries to OCSP responders.

### **[-ocsp-max-response-age <unsigned32\_or\_unlimited>] - Maximum Allowable Age for OCSP Responses (secs)**

Filters the display of SSL configuration according to the maximum allowable age (freshness) in seconds for the OCSP responses.

### **[-ocsp-max-response-time-skew <[<integer>h][<integer>m][<integer>s]>] - Maximum Allowable Time Skew for OCSP Response Validation**

Filters the display of SSL configuration according to the maximum allowable time difference for OCSP responses (when validating their ThisUpdate and NextUpdate fields).

### **[-ocsp-use-request-nonce {true|false}] - Use a NONCE within OCSP Queries**

Filters the display of SSL configuration by specifying whether the queries to the OCSP responders should contain a NONCE or not.

A NONCE is a unique identifier included in each OCSP request or OCSP response to prevent a replay attack.

## Examples

The following example displays the configured certificates for Vservers.

```
cluster1::security ssl> show
      Serial                Server Client
Vserver Number Common Name Enabled Enabled
-----
cluster1 516C3CB3
           cluster1.company.com      true   true
vs0      516816D4
           vs0.company.com           true   false
2 entries were displayed.
```

- [vserver services web show](#)

# security tpm show

Display the status of TPM

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

This command displays information about the status of the Trusted Platform Module (TPM) device. By default, this command displays the following information:

- Node name
- Availability of the device
- State of the device, if available
- Firmware version
- Firmware upgrade counter

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ -instance ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[ -node {<nodename>|local} ] - Node**

Selects the nodes that match this parameter value

**[ -is-available {yes|no} ] - Is TPM Available?**

Selects the nodes that match this parameter value.

- yes - The TPM device is mounted and available.
- no - The node does not support a TPM.

**[ -is-active {yes|no} ] - Is TPM Active?**

Selects the nodes that match this parameter value.

- yes - The TPM device is available and active.
- no - if **-is-available** parameter is **yes**, the TPM device is mounted and available but is not responding to TPM commands.

**[ -version <text> ] - Firmware Version**

Selects the nodes that match this firmware version.

**[-upgrade-count <integer>] - Firmware Counter**

Selects the nodes that match the given number of firmware upgrade tries left.

**[-sym-key-size <integer>] - Size of Primary Symmetric Key**

Selects the nodes that match the given symmetric key size for the primary symmetric key.

## Examples

```
cluster1::> security tpm show
```

Node	Available?	Active?	Firmware Version	Firmware Counter
node1	yes	yes	2.5	64
node2	yes	yes	2.5	64

2 entries were displayed.

# snaplock compliance-clock initialize

Initializes the node ComplianceClock

**Availability:** This command is available to *cluster* administrators at the *admin* privilege level.

## Description

`snaplock compliance-clock initialize` command is used to initialize System ComplianceClock from the system clock. System ComplianceClock can be initialized only once by the user. Once initialized, user cannot make any changes to the System ComplianceClock. Hence, user should ensure that system clock is correct before initializing the System ComplianceClock.

## Parameters

**-node {<nodename>|local} - Node**

Specifies the name of the node on which System ComplianceClock needs to be initialized.

**[-force <>true>] - Forces Initialization**

If you use this parameter, it will suppress the warning message during **snaplock compliance-clock initialize** operation.

## Examples

```
cluster-1::> snaplock compliance-clock initialize -node node1
```

```
Warning: You are about to initialize the secure ComplianceClock of the node
node1 to the current value of the node's system clock. This
```

```
procedure can be performed only once on a given node, so you should
ensure that the system time is set correctly before proceeding.
```

```
The current node's system clock is: Wed Nov 26 16:18:30 IST 2014
```

```
Do you want to continue? {y|n}: y
```

```
cluster-1::>
```

## snaplock compliance-clock show

Displays the node ComplianceClock

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

### Description

The `snaplock compliance-clock show` command will display System ComplianceClock of the nodes in the cluster. It will display the following information:

- Node name
- ComplianceClock Time

### Parameters

`{ [-fields <fieldname>, ... ] }`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

`{ [-instance ] }`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

`{ [-node {<nodename>|local} ] } - Node`

If this parameter is specified, the command will display ComplianceClock for that particular node only.

`{ [-time <text> ] } - ComplianceClock Time of the Node`

If this parameter is specified, the command will display nodes having the same `-time` value.

### Examples

```
cluster1::> snaplock compliance-clock show
Node                ComplianceClock Time
-----
```

```
node1          Mon Jan 12 11:34:15 IST 2015 +05:30
node2          Mon Jan 12 11:34:10 IST 2015 +05:30
2 entries were displayed.
```

```
cluster1::> snaplock compliance-clock show -node node1
Node          ComplianceClock Time
-----
node1         Mon Jan 12 11:34:45 IST 2015 +05:30
```

## snaplock compliance-clock ntp modify

Modify SnapLock ComplianceClock synchronization setting

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

The `snaplock compliance-clock ntp modify` command modifies the option to enable or disable the SnapLock ComplianceClock synchronization with the system time. The ComplianceClock is synchronized only when an NTP server has been configured so that the system time follows the NTP time and the skew between the ComplianceClock time and the system time is greater than 1 day.

### Parameters

`[-is-sync-enabled {true|false}]` - Enable ComplianceClock sync to NTP system time

Specifies whether synchronization should be enabled or not. This is a cluster wide option.

### Examples

```
cluster1::> snaplock compliance-clock ntp modify -is-sync-enabled true
```

## snaplock compliance-clock ntp show

Display SnapLock ComplianceClock synchronization setting

**Availability:** This command is available to *cluster* administrators at the *advanced* privilege level.

### Description

The `snaplock compliance-clock ntp show` command will display ComplianceClock synchronization setting. It will display the following information:

- **is-sync-enabled** - Displays if the option to synchronize the ComplianceClock with system time has been enabled or not.

## Examples

```
cluster1::> snaplock compliance-clock ntp show
Enable clock sync to NTP system time: true
```

# snaplock event-retention abort

Abort an Event Based Retention policy operation.

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **snaplock event-retention abort** is used to abort an ongoing Event Based Retention (EBR) operation. This command only aborts the operations that have not yet completed. Only a user with security login role **vsadmin-snaplock** is allowed to perform this operation.

## Parameters

**-vserver <vserver name> - Vserver Name**

Specifies the vserver on which the EBR operation is running.

**-operation-id <integer> - Operation ID**

Specifies the operation ID of the EBR operation that needs to be aborted.

## Examples

The following example aborts an ongoing EBR operation with operation-id **16842754** :

```
vs1::> snaplock event-retention abort -operation-id 16842754
vs1::>
```

# snaplock event-retention apply

Apply an Event Based Retention policy on all files within a user specified path.

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **snaplock event-retention apply** command starts a new operation to apply the specified Event Based Retention (EBR) policy to all files in the specified path. If a file is a regular file, it will be made a WORM file and retained for a retention-period as defined by the specified policy name. If a file is already WORM, its retention time will be extended to a retention-period as defined by the specified policy name, starting from the current time. The retention time of a file will be extended only if the file's current retention time is less than the new retention time value to be set. Only a user with security login role **vsadmin-snaplock** is allowed to perform this operation.

## Parameters

### **-vserver <vserver name> - Vserver Name**

Specifies the name of the Vserver which has the EBR policy defined to be applied on one or more files.

### **-policy-name <text> - Policy Name**

Specifies the name of the EBR policy to be applied on one or more files.

### **-volume <volume name> - Volume**

Specifies the name of the SnapLock volume containing a file path or a directory path as specified by the path parameter. The specified EBR policy is applied to one or more files depending on the value of path.

### **-path <text> - Path**

Specifies the path relative to the output volume root, of the form `"/path"`. The path can be path to a file or a directory. The EBR policy is applied to all files under the specified path. To apply the EBR policy to all files in a volume, specify the path as `"/"`.

## Examples

The following example starts an EBR operation to apply a policy on files for specified volume:

```
vs1::> snaplock event-retention apply -policy-name p1 -volume slc -path /  
SnapLock event based retention operation is queued. Run "snaplock  
event-retention show -operation-id 16842754 -instance" to view the operation status.
```

## snaplock event-retention show-vservers

Show Vservers with SnapLock Event Based Retention policies

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `snaplock event-retention show-vservers` command is used to display the Vservers that have SnapLock Event Based Retention (EBR) policies created.

## Parameters

`[-fields <fieldname>,...]`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

## Examples

The following example displays all Vservers that have SnapLock EBR policies:

```
cluster-1::*> snaplock event-retention show-vservers
Vserver
-----
vs1
```

# snaplock event-retention show

Show status of Event Based Retention operation

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `snaplock event-retention show` command displays the status of an Event Based Retention (EBR) operation. Information about completed operations will be cleaned up after an hour after completion. Only a user with security login role **vsadmin-snaplock** is allowed to perform this operation.

## Parameters

`{[-fields <fieldname>,...]}`

If you specify the `-fields <fieldname>, ...` parameter, the command output also includes the specified field or fields. You can use `'-fields ?'` to display the fields to specify.

`[-instance ]}`

If you specify the `-instance` parameter, the command displays detailed information about all fields.

**[-vserver <vserver name>] - Vserver Name**

If this parameter is specified, the command displays all EBR operations that match the specified Vserver.

**[-operation-id <integer>] - Operation ID**

If this parameter is specified, the command displays all EBR operations that match the specified operation ID.

**[-volume <volume name>] - Volume Name**

If this parameter is specified, the command displays all EBR operations that match the specified volume. The parameter specifies the volume on which EBR operation is running or has completed.

**[-path <text>] - Path**

If this parameter is specified, the command displays all EBR operations that match the specified path. The parameter specifies the path on which EBR operation is running or has completed.

**[-policy-name <text>] - Policy Name**

If this parameter is specified, the command displays all EBR operations that match the specified policy name. The parameter specifies the EBR policy name.

**[-retention-period {{<integer> seconds|minutes|hours|days|months|years} | infinite}] - Retention Period**

If this parameter is specified, the command displays all EBR operations that match the specified retention period. The parameter specifies the retention period of the EBR policy.

**[-num-files-processed <integer>] - Number of Files Processed**

If this parameter is specified, the command displays all EBR operations that match the specified number of processed files. The parameter specifies the number of files on which EBR policy was applied successfully.

**[-num-files-failed <integer>] - Number of Files Failed**

If this parameter is specified, the command displays all EBR operations that match the specified number of failed files. The parameter specifies the number of files on which the application of EBR policy failed.

**[-num-files-skipped <integer>] - Number of Files Skipped**

If this parameter is specified, the command displays all EBR operations that match the specified number of skipped files. The parameter specifies the number of files on which the application of EBR policy was skipped. A file that is under legal-hold will be skipped. If the retention time of a file is being shortened as a result of applying the EBR policy, that file will also be skipped.

**[-num-inodes-ignored <integer>] - Number of Inodes Ignored**

If this parameter is specified, the command displays all EBR operations that match the specified number of ignored inodes. The parameter specifies the number of inodes on which the application of EBR policy was not attempted because they were not regular files.

**[-operation-status {Unknown|In-Progress|Failed|Aborting|Completed}] - Operation Status**

If this parameter is specified, the command displays all EBR operations that match the specified operation status. The parameter specifies the operation status of an EBR operation.

**[-status-details <text>] - Status Details**

If this parameter is specified, the command displays all EBR operations that match the specified status details. The parameter specifies the status details of an EBR operation.

## Examples

The following examples show the status of EBR operations for Vserver "vs1" and volume "slc" and the status of event-retention operation for operation ID **16842753** respectively.

```
vs1::*> snaplock event-retention operation show -volume slc
      Operation ID  Vserver      Volume      Operation Status
      -----
      16842753      vs1         slc         Completed
      16842754      vs1         slc         In-progress
vs1::*> snaplock event-retention operation show -operation-id 16842753
Operation ID: 16842753
      Vserver: vs1
      Volume: slc
      Path: /vol/slc/d1
      Policy Name: p1
      Retention Period: 10 years
Number of Files Processed: 50
Number of Files Failed: 0
Number of Inodes Ignored: 2
      Operation Status: Completed
      Status Details: No error
```

## snaplock event-retention policy create

Create SnapLock Event Based Retention policies for a Vserver

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **snaplock event-retention policy create** command is used to create Event Based Retention (EBR) policies for a Vserver. A policy consists of a **policy-name** and a **retention-period**. Only a user with security login role **vsadmin-snaplock** is allowed to perform this operation.

## Parameters

### -vserver <vserver name> - Vserver Name

Specifies the name of the Vserver for which a policy needs to be created.

### -name <text> - Policy Name

Specifies the name of the EBR policy to be created.

### -retention-period {{{integer} seconds|minutes|hours|days|months|years} | infinite} - Event Retention Period

Specifies the retention period for an EBR policy.

## Examples

The following example creates a new EBR policy "p1" for Vserver "vs1" with a retention period of "10 years":

```
vs1::> snaplock event-retention policy create -name p1 -retention-period "10 years"
```

# snaplock event-retention policy delete

Delete SnapLock Event Based Retention policies for a Vserver

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **snaplock event-retention policy delete** command is used to delete Event Based Retention (EBR) policies for a Vserver. Only a user with security login role **vsadmin-snaplock** is allowed to perform this operation.

## Parameters

### -vserver <vserver name> - Vserver Name

If this parameter is specified, the command deletes all EBR policies that match the specified Vserver.

### -name <text> - Policy Name

If this parameter is specified, the command deletes all EBR policies that match the specified **name**.

## Examples

The following example deletes retention policy "p1" for Vserver "vs1":

```
vs1::> snaplock event-retention policy delete -name p1
```

## snaplock event-retention policy modify

Modify SnapLock Event Based Retention policies for a Vserver

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

### Description

The **snaplock event-retention policy modify** command is used to modify the retention period of an Event Based Retention (EBR) policy for a Vserver. Only a user with security login role **vsadmin-snaplock** is allowed to perform this operation.

### Parameters

**-vserver <vserver name> - Vserver Name**

Specifies the name of the Vserver for which retention period of a policy needs to be modified.

**-name <text> - Policy Name**

Specifies the name of the EBR policy for which the retention period needs to be modified.

**[-retention-period {{<integer> seconds|minutes|hours|days|months|years} | infinite}] - Event Retention Period**

Specifies the new value of retention period.

### Examples

The following example modifies the retention period of policy "p1" for Vserver "vs1" to **"5 years"** :

```
vs1::> snaplock event-retention policy modify -name p1 -retention-period "5 years"
```

## snaplock event-retention policy show

Show SnapLock Event Based Retention policies for a Vserver

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **snaplock event-retention policy show** command is used to show Event Based Retention (EBR) policies for a Vserver. A policy consists of a **policy-name** and a **retention-period**. The command output depends on the parameter or parameters specified. If no parameters are specified, all policies for all vservers will be displayed. If one or more parameters are specified, only those entries matching the specified values will be displayed. Only a user with security login role **vsadmin-snaplock** is allowed to perform this operation.

## Parameters

**{ [-fields <fieldname>, ... ] }**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[ [-instance ] ] }**

If you specify the **-instance** parameter, the command displays detailed information about all fields.

**[-vserver <vserver name>] - Vserver Name**

If this parameter is specified, the command displays all EBR policies that match the specified Vserver.

**[-name <text>] - Policy Name**

If this parameter is specified, the command displays all EBR policies that match the specified **name**.

**[-retention-period {{<integer> seconds|minutes|hours|days|months|years} | infinite}] - Event Retention Period**

If this parameter is specified, the command displays all EBR policies that match the specified **retention-period**.

## Examples

The following example displays all event-retention policies for vserver "vs1":

```
vs1::> snaplock event-retention policy show
```

Vserver	Name	Retention Period
vs1	p1	10 years
vs1	p2	5 years

## snaplock legal-hold abort

Abort Snaplock legal-hold operation.

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **snaplock legal-hold abort** is used to abort an ongoing legal-hold operation. The type of legal-hold operations that can be aborted using this command are *begin*, *end* and *dump-files*. This command only aborts operations that have not yet completed. Only a user with security login role **vsadmin-snaplock** is allowed to perform this operation.

## Parameters

**-vserver <vserver name> - Vserver Name**

Specifies the vserver on which the legal-hold operation is running.

**-operation-id <integer> - Operation ID**

Specifies the operation ID of the legal-hold operation to be aborted.

## Examples

The following example aborts an ongoing legal-hold operation with operation-id **16842754** :

```
vs1::> snaplock legal-hold abort -operation-id 16842754
vs1::>
```

## snaplock legal-hold begin

Starts an operation to place files under legal-hold in the user specified path on a SnapLock compliance volume.

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **snaplock legal-hold begin** command is used to place specified file or files under legal-hold for a given litigation. Only a user with security login role **vsadmin-snaplock** is allowed to perform this operation.

## Parameters

**-vserver <vserver name> - Vserver Name**

Specifies the name of the Vserver which owns the volume. The specified file or files to be placed

under legal-hold reside on this volume.

### **-litigation-name <text> - Litigation Name**

Specifies the name of the litigation for which the file or files have to be placed under legal-hold.

### **-volume <volume name> - Volume**

Specifies the name of the SnapLock compliance volume on which the file or files to be placed under legal-hold reside.

### **-path <text> - Path**

Specifies a path relative to the volume root. The path can be either a file path of the single file to be placed under legal-hold or a directory path where all regular files under it must be placed under legal-hold.

## Examples

The following example starts a legal-hold begin operation on file **file1** in volume **slc\_vol1** :

```
vs1::> snaplock legal-hold begin -litigation-name litigation1 -volume slc_vol1 -path /file1
SnapLock legal-hold begin operation is queued. Run "snaplock legal-hold show -operation-id 16842773 -instance" to view the operation status.
```

The following example starts a legal-hold begin operation on all files in the volume **slc\_vol1** :

```
vs1::> snaplock legal-hold begin -litigation-name litigation1 -volume slc_vol1 -path /
SnapLock legal-hold begin operation is queued. Run "snaplock legal-hold show -operation-id 16842775 -instance" to view the operation status.
```

## snaplock legal-hold dump-files

Dump list of files under legal-hold to specified output path.

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **snaplock legal-hold dump-files** is used to dump the list of files under legal-hold for a given vserver, volume and litigation to an auto-generated file in the user specified path. Only a user with security login role **vsadmin-snaplock** is allowed to perform this operation.

## Parameters

### **-vserver <vserver name> - Vserver Name**

Specifies the name of the Vserver for which the list of files under legal-hold is to be dumped.

### **-litigation-name <text> - Litigation Name**

Specifies the name of the litigation for which the list of files under legal-hold is to be dumped.

### **-volume <volume name> - Volume Name**

Specifies the name of the SnapLock compliance volume for which the list of files under legal-hold is to be dumped.

### **-output-volume <volume name> - Output Volume Name**

Specifies the name of the output volume containing the output directory path where the list of files under legal-hold is to be dumped. The output volume must be a regular read-write volume.

### **-output-directory-path <text> - Path Relative to Output Volume Root**

Specifies the output directory path relative to the output volume root, where the list of files under legal-hold is to be dumped. The output directory path should be of the form "/directory-path". If output needs to be dumped on the volume root, specify the path as "/".

## Examples

The following example starts a legal-hold dump-files operation:

```
vs1::> snaplock legal-hold dump-files -volume vol1_slc -litigation-name lit1 -output
-volume vol1 -output-directory-path /d1
      SnapLock legal-hold dump-files operation is queued. Run "snaplock legal-
hold show -operation-id 16842754 -instance" to view the operation status.
vs1::>
```

## snaplock legal-hold dump-litigations

Dump list of litigations for a given Vserver to specified output path.

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **snaplock legal-hold dump-litigations** is used to dump the list of litigations for a given vserver to a user specified path. Under the user specified path, we create a directory with a unique name. Under the user specified path, a directory with an auto-generated name is created. Under this directory, multiple files are created. Each file represents a unique litigation name that was found in the given vserver. Each file contains a list of volume names that have files under legal-hold for that

given litigation. For example, if the file name is "lit1" and the contents of the file are "volume1" and "volume2", then it indicates that both these volumes have files under legal-hold for litigation "lit1". Only a user with security login role **vsadmin-snaplock** is allowed to perform this operation.

## Parameters

### **-vserver <vserver name> - Vserver Name**

Specifies the name of the Vserver for which the list of litigations is to be dumped.

### **[-volume <volume name>] - Volume Name**

If this parameter is specified, the command displays the list of litigations for volume that matches the specified value. The volume must be of type SnapLock compliance.

### **-output-volume <volume name> - Output Volume Name**

Specifies the name of the output volume containing the output directory path where the list of litigations is to be dumped. The output volume must be a regular read-write volume.

### **-output-directory-path <text> - Path Relative to Output Volume Root**

Specifies the output directory path relative to the volume root, where the list of litigations is to be dumped. The output directory path should be of the form "/directory-path". If output needs to be dumped to the volume root, specify the path as "/".

## Examples

The following example starts a legal-hold dump-litigations job:

```
vs1::> snaplock legal-hold dump-litigations -output-volume vol1 -output-directory-path /d1
          Dump Litigations job for Vserver "vs1" has been queued. Run "job show -id 22 -instance" to view the status.
vs1::>
```

## snaplock legal-hold end

Starts an operation to release legal-hold on files in the user specified path on a SnapLock compliance volume.

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **snaplock legal-hold end** command is used to release legal-hold on specified file or files for a given litigation. Only a user with security login role **vsadmin-snaplock** is allowed to perform this operation.

## Parameters

### **-vserver <vserver name> - Vserver Name**

Specifies the name of the Vserver which owns the volume. The specified file or files to be released from legal-hold reside on this volume.

### **-litigation-name <text> - Litigation Name**

Specifies the name of the litigation for which the file or files have to release from legal-hold.

### **-volume <volume name> - Volume**

Specifies the name of the SnapLock compliance volume on which the file or files to be released from legal-hold reside.

### **-path <text> - Path**

Specifies a path relative to the volume root. The path can be either a file path of the single file to be released from legal-hold or a directory path where all regular files under it must be released from legal-hold.

## Examples

The following example starts a legal-hold end operation on file **file1** in volume **slc\_vol1** :

```
vs1::> snaplock legal-hold end -litigation-name litigation1 -volume slc_vol1 -path /file1
SnapLock legal-hold end operation is queued. Run "snaplock legal-hold show -operation -id 16842773 -instance" to view the operation status.
```

The following example starts a legal-hold end operation on all files in the volume **slc\_vol1** :

```
vs1::> snaplock legal-hold end -litigation-name litigation1 -volume slc_vol1 -path /
SnapLock legal-hold end operation is queued. Run "snaplock legal-hold show -operation -id 16842775 -instance" to view the operation status.
```

## snaplock legal-hold show

Show status of a legal-hold operation.

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **snaplock legal-hold show** command displays the status of a legal-hold operation. Information about completed operations will be cleaned up after an hour of completion. Only a user with security

login role **vsadmin-snaplock** is allowed to perform this operation.

## Parameters

### { [-fields <fieldname>,...]

If you specify the **-fields <fieldname>**, ... parameter, the command output also includes the specified field or fields. You can use '-fields ?' to display the fields to specify.

### [-instance ]}

If you specify the **-instance** parameter, the command displays detailed information about all fields.

### [-vserver <vserver name>] - Vserver Name

If this parameter is specified, the command displays all legal-hold operations that match the specified Vserver.

### [-operation-id <integer>] - Operation ID

If this parameter is specified, the command displays all legal-hold operations that match the specified operation ID.

### [-volume <volume name>] - Volume Name

If this parameter is specified, the command displays all legal-hold operations that match the specified volume. The parameter specifies the volume on which legal-hold operation is running or has completed.

### [-path <text>] - Path

If this parameter is specified, the command displays all legal-hold operations that match the specified path. The parameter specifies the path on which legal-hold operation is running or has completed.

### [-litigation-name <text>] - Litigation Name

If this parameter is specified, the command displays all legal-hold operations that match the specified litigation name. The parameter specifies the legal-hold litigation name.

### [-operation-type {unknown|begin|end|dump-files}] - Operation Type

If this parameter is specified, the command displays all legal-hold operations that match the specified operation type. The parameter specifies the type of legal-hold operation.

### [-operation-status {Unknown|In-Progress|Failed|Aborting|Completed}] - Operation Status

If this parameter is specified, the command displays all legal-hold operations that match the specified operation status. The parameter specifies the status of legal-hold operation.

### [-num-files-processed <integer>] - Number of Files Processed

If this parameter is specified, the command displays all legal-hold operations that match the specified number of files processed. The parameter specifies the number of files on which legal-hold operation was successful.

**[-num-files-failed <integer>] - Number of Files Failed**

If this parameter is specified, the command displays all legal-hold operations that match the specified number of files failed. The parameter specifies the number of files on which legal-hold operation failed.

**[-num-files-skipped <integer>] - Number of Files Skipped**

If this parameter is specified, the command displays all legal-hold operations that match the specified number of files skipped.

The parameter specifies the number of files on which legal-hold begin operation was skipped. The legal-hold begin operation is skipped on a file if it is already under hold for a given litigation or if it is a hard link to a file that is already under hold for a given litigation.

**[-num-inodes-ignored <integer>] - Number of Inodes Ignored**

If this parameter is specified, the command displays all legal-hold operations that match the specified number of inodes ignored. The parameter specifies the number of inodes on which the legal-hold operation was not attempted because they were not regular files.

**[-status-details <text>] - Status Details**

If this parameter is specified, the command displays all legal-hold operations that match the specified status details. The parameter specifies the status details of an legal-hold operation.

## Examples

The following examples show the status of legal-hold operations for Vserver **vs1** and volume **slc\_vol1** and the status of legal-hold operation for operation ID **16842786** respectively:

```
vs1::> snaplock legal-hold show -volume slc_vol1
```

Operation	Operation ID	Vserver	Volume	Operation Status
begin	16842784	vs1	slc_vol1	Completed
begin	16842786	vs1	slc_vol1	Completed
begin	16842788	vs1	slc_vol1	In-Progress
dump-files	16842790	vs1	slc_vol1	Completed
end	16842794	vs1	slc_vol1	Completed

```
5 entries were displayed.
```

```
vs1::> snaplock legal-hold show -operation-id 16842786
```

```
Vserver: vs1
      Volume: slc_vol1
      Operation ID: 16842786
      Litigation Name: litigation1
```

```
Path: /
Operation Type: begin
Status: Completed
Number of Files Processed: 100
Number of Files Failed: 15
Number of Files Skipped: 20
Number of Inodes Ignored: 0
Status Details: No error
```

## snaplock log create

Create audit log configuration for a Vserver.

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

### Description

The `snaplock log create` command is used to create a SnapLock log configuration for the Vserver. A SnapLock log configuration consists of volume to store the log, the maximum size of the log file, and the default period of time for which the log file should be retained.

### Parameters

**-vserver <vserver name> - Vserver Name**

Specifies the name of the Vserver for which the configuration needs to be created.

**-volume <volume name> - Log Volume Name**

Specifies the name of the volume that is used for logging. This must be a SnapLock Compliance volume.

**[-max-log-size {<integer>[KB|MB|GB|TB|PB]}] - Maximum Size of Log File**

Specifies the maximum size of the log file. Once a log file reaches this limit, it is archived and a new log file is created. This parameter is optional. The default value is **10MB**.

**[-default-retention-period {{<integer> seconds|minutes|hours|days|months|years} | infinite}] - Default Log Record Retention Period**

Specifies the default period of time a record (which is logged) is retained. This parameter is optional. The default value is **"6 months"**.

### Examples

```
cluster1::> snaplock log create -volume vol1 -max-log-size 50MB -default-retention
```

```
-period "1 year" -vserver vs1  
[Job 47] Job succeeded: SnapLock log created for Vserver "vs1".
```

## snaplock log delete

Delete audit log configuration for a Vserver.

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

### Description

The **snaplock log delete** command deletes the SnapLock log configuration associated with the Vserver. This command closes all the active log files in the log volume and mark the volume as disabled for SnapLock logging.

### Parameters

**-vserver <vserver name> - Vserver Name**

Specifies the name of the Vserver whose SnapLock log configuration is deleted.

### Examples

```
cluster1::> snaplock log delete -vserver vs1  
[Job 47] Job succeeded: SnapLock log deleted for Vserver "vs1".
```

## snaplock log modify

Modify audit log configuration for a Vserver.

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

### Description

The **snaplock log modify** command modifies the SnapLock log configuration of the Vserver. Log volume, maximum size of log file, and default retention period can be modified. If the log volume is modified, then the active log files in the existing log volume is closed and the log volume is marked as disabled for logging. The new log volume is enabled for logging.

## Parameters

### **-vserver <vserver name> - Vserver Name**

Specifies the name of the Vserver for which the SnapLock log configuration needs to be modified.

### **[-volume <volume name>] - Log Volume Name**

Specifies the new log volume that is configured for this Vserver for logging.

### **[-max-log-size {<integer>[KB|MB|GB|TB|PB]}] - Maximum Size of Log File**

Specifies the new value for maximum log file size.

### **[-default-retention-period {{<integer> seconds|minutes|hours|days|months|years} | infinite}] - Default Log Record Retention Period**

Specifies the new value for default retention period.

## Examples

```
cluster1::> snaplock log modify -volume vol1 -vserver vs1 -max-log-size 15MB
[Job 48] Job succeeded: SnapLock log modified for Vserver "vs1".
```

## snaplock log show

Display audit log configuration.

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **snaplock log show** command displays the following information about the SnapLock log infrastructure:

- Vserver name
- Volume name
- Maximum log size
- Default retention period

## Parameters

### **{ [-fields <fieldname>, ...]**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[`-instance` ]}**

If you specify the `-instance` parameter, the command displays detailed information about all fields.

**[`-vserver <vserver name>`] - Vserver Name**

If this parameter is specified, the command displays the log information for Vservers that match the specified value.

**[`-volume <volume name>`] - Log Volume Name**

If this parameter is specified, the command displays the log configuration for volumes that match the specified value.

**[`-max-log-size {<integer>[KB|MB|GB|TB|PB]}`] - Maximum Size of Log File**

If this parameter is specified, the command displays the log configuration with a matching `-max-log-size` value.

**[`-default-retention-period {{<integer> seconds|minutes|hours|days|months|years} | infinite}`] - Default Log Record Retention Period**

If this parameter is specified, the command displays the log configuration with a matching `-default-retention-period` value.

## Examples

```
cluster1::> snaplock log show -vserver vs1
Vserver Name           : vs1
  Log Volume Name      : 15MB
  Maximum Size of Log File : 15MB
  Default Log Record Retention Period : 6 months
```

```
cluster1::> snaplock log show
  Vserver           Volume           Maximum Size           Retention Period
  -----
  vs1              vol1              15MB                  6 months
```

# snaplock log file archive

## Archive Active Log Files in Log Volume

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The `snaplock log file archive` command archives the currently active log file by closing it and

creating a new active log file. If base-name is not provided, the command archives all active log files associated with the Vserver. Otherwise, the command archives the active log file associated with the base-name provided.

## Parameters

### **-vserver <vserver name> - Vserver Name**

Specifies the name of the Vserver for which active log files need to be archived.

### **[-base-name {privileged-delete | system | legal-hold}] - Base Name of Log File**

Specifies the log base-name, whose active log file needs to be archived. The base-name is the name of the source of log records. Valid base-names are **system**, **privileged-delete** and **legal-hold**. Each base-name has its own directory in which log files containing log records generated by base-name are stored.

## Examples

```
cluster1::> snaplock log archive -vserver vs1
[Job 48] Job succeeded: SnapLock log archived for Vserver "vs1".
```

## snaplock log file show

Display audit log file information.

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **snaplock log file show** command displays the following information about the log files:

- Vserver name
- Volume name
- File path
- Expiry time of the file
- File size

## Parameters

**{ [-fields <fieldname>, ... ]**

If you specify the **-fields <fieldname>, ...** parameter, the command output also includes the specified field or fields. You can use **'-fields ?'** to display the fields to specify.

**[`-instance`] }**

If you specify the `-instance` parameter, the command displays detailed information about all fields.

**[`-vserver <vserver name>`] - Vserver Name**

If this parameter is specified, then log files in the Vserver that match the specified value is displayed.

**[`-base-name {privileged-delete | system | legal-hold}`] - Base Name of Log File**

If this parameter is specified, then the log files having a matching `-base-name` is displayed.

**[`-volume <volume name>`] - Log Volume Name**

If this parameter is specified, then the log files in volumes that match the specified value are shown.

**[`-file-path <text>`] - Log File Path**

If this parameter is specified, then the log files that match the specified value are displayed.

**[`-expiry-time <text>`] - Log File Expiry Time**

If this parameter is specified, then the log files having a matching `-expiry-time` value are displayed.

**[`-file-size {<integer>[KB|MB|GB|TB|PB]}`] - File Size**

If this parameter is specified, then the log files having a matching `-file-size` value are displayed.

## Examples

```
cluster1::> snaplock log file show
  Vserver          Volume          Base Name          File Path
  -----
  vs1              vol1              system
/vol/vol1/snaplock_log/system_logs/20160120_183756_GMT-present
```

```
cluster1::> snaplock log file show -vserver vs1 -base-name system
Vserver      : vs1
  Volume     : vol1
  Base Name  : system
  File Path  : /vol/vol1/snaplock_log/system_logs/20160120_183756_GMT-present
  Expiry Time : Wed Jul 20 18:37:56 GMT 2016
  File Size  : 560B
```

## snapmirror abort

Abort an active transfer

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **snapmirror abort** command stops SnapMirror transfers that might have started and not completed. A SnapMirror transfer is an operation on a given SnapMirror relationship and the relationship is identified by its destination endpoint, which can be a volume, a Vserver, or a non-Data ONTAP endpoint. You identify the SnapMirror relationship with this command and the command aborts the transfer for the relationship. For load-sharing mirrors, the command also aborts transfers for other relationships that are part of the same load-sharing set. For SolidFire destination endpoints, the **snapmirror abort** command is only supported if the endpoint is in a SnapMirror relationship.

Load-sharing mirrors are either up to date and serving data to clients, or they are lagging and not serving data to clients. If the **snapmirror abort** command identifies an up-to-date load-sharing mirror, then SnapMirror transfers to the up-to-date load-sharing mirror and associated up-to-date load-sharing mirrors in the set of load-sharing mirrors are aborted. If the **snapmirror abort** command identifies a lagging load-sharing mirror, then only the SnapMirror transfer associated with the lagging load-sharing mirror is aborted.

After the **snapmirror abort** command successfully completes its operation, the volume on the receiving side of the transfer might contain a restart checkpoint. The restart checkpoint can be used by a subsequent transfer to restart and continue the aborted SnapMirror transfer.

This command is supported for SnapMirror relationships with the field **"Relationship Capability"** showing as either **"8.2 and above"** or **"Pre 8.2"** in the output of the [snapmirror show](#) command.

This command is not supported for SnapMirror Business Continuity (SMBC) relationships with policy of type **automated-failover** in admin privilege level.

The use of wildcards in parameter values is not supported from the source Vserver or cluster for relationships with **"Relationship Capability"** of **"8.2 and above"**.

You can use this command from the source or the destination Vserver or cluster for FlexVol volume relationships.

For SnapMirror Synchronous relationships, this command aborts any ongoing transfer and takes the relationship **OutOfSync**. This can result in primary client IO failure for relationships with a policy of type **strict-sync-mirror**. Instead, the best practice recommendation is to use the [snapmirror quiesce](#) command.

Beginning with ONTAP 9.12.1, for SnapMirror Synchronous relationships on platforms that support NDO, **snapmirror abort** triggered in **"InSync"** state will not change the relationship status to **"OutOfSync"**. Instead, it will internally trigger the feature **"Fast Resync"** which will try to keep the relationship status **"InSync"**.

For Vserver SnapMirror relationships, this command must be run only from the cluster containing the destination Vserver.

## Parameters

{ [-S, -source-path

{<[vserver:][volume]>|<[[cluster:]/vserver/]volume>|<hostip:/lun/name>|<hostip:/share/share-name>|<[vserver:]/cg/[cgname]>} - Source Path

This parameter specifies the source endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or the volume (volume). To support relationships with **"Relationship Capability" of "Pre 8.2"**, a format which also includes the name of the cluster (cluster) is provided. The **"Pre 8.2"** format cannot be used when operating in a Vserver context on relationships with **"Relationship Capability" of "8.2 and above"**. For SnapMirror relationships with an AltaVault source, the source endpoint is specified in the form **hostip:/share/share-name**. For SnapMirror relationships with a SolidFire source, the source endpoint is specified in the form **hostip:/lun/name**.

| [-source-cluster <Cluster name>] - Source Cluster

Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the **-source-vserver** and **-source-volume** parameters must also be specified. This parameter is only applicable for relationships with **"Relationship Capability" of "Pre 8.2"**. This parameter cannot be specified when operating in a Vserver context on relationships with **"Relationship Capability" of "8.2 and above"**.

[-source-vserver <vserver name>] - Source Vserver

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters **-source-volume** and for relationships with **"Relationship Capability" of "Pre 8.2"**, **-source-cluster** must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

[-source-volume <volume name>] - Source Volume }

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters **-source-vserver** and for relationships with **"Relationship Capability" of "Pre 8.2"**, **-source-cluster** must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

{ -destination-path

{<[vserver:][volume]>|<[[cluster:]/vserver/]volume>|<hostip:/lun/name>|<hostip:/share/share-name>|<[vserver:]/cg/[cgname]>} - Destination Path

This parameter specifies the destination endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with **"Relationship Capability" of "Pre 8.2"**, a format which also includes the name of the cluster (cluster) is provided. The **"Pre 8.2"** format cannot be used when operating in a Vserver context on relationships with **"Relationship Capability" of "8.2 and above"**. For SnapMirror relationships with AltaVault destinations, the destination endpoint is specified in the form **hostip:/share/share-name**. For relationships with SolidFire destinations, the destination endpoint is specified in the form **hostip:/lun/name**.

| [-destination-cluster <Cluster name>] - Destination Cluster

Specifies the destination cluster of the SnapMirror relationship. If this parameter is specified,

parameters **-destination-vserver** and **-destination-volume** must also be specified. This parameter is only applicable for relationships with **"Relationship Capability"** of **"Pre 8.2"** . This parameter cannot be specified when operating in a Vserver context on relationships with **"Relationship Capability"** of **"8.2 and above"** .

#### **-destination-vserver <vserver name> - Destination Vserver**

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters **-destination-volume** and for relationships with **"Relationship Capability"** of **"Pre 8.2"** , **-destination-cluster** must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

#### **-destination-volume <volume name> - Destination Volume }**

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameters **-destination-vserver** and for relationships with **"Relationship Capability"** of **"Pre 8.2"** , **-destination-cluster** must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

#### **[-h, -hard <true>] - Discard Restart Checkpoint**

If this option is specified true, the restart checkpoint is discarded and the destination volume is restored to the last Snapshot copy that was successfully transferred. You can use the **-hard** option to discard the restart checkpoint of a previous transfer attempt which forces the subsequent transfer to start with a fresh Snapshot copy on the destination volume. This option can only be used from the destination Vserver or cluster. This parameter is not supported for relationships with non-Data ONTAP endpoints.

#### **[-w, -foreground <true>] - Foreground Process**

This specifies whether the operation runs as a foreground process. If this parameter is specified, the default setting is **true** (the operation runs in the foreground). When set to **true** , the command will not return until the process completes. This parameter is only applicable to relationships with **"Relationship Capability"** of **"Pre 8.2"** .

## Examples

To stop the active SnapMirror replication to the destination volume **vs2.example.com:dept\_eng\_dp\_mirror1** , type the following command:

```
vs2.example.com::> snapmirror abort -destination-path  
vs2.example.com:dept_eng_dp_mirror1
```

For relationships with **"Relationship Capability"** of **"Pre 8.2"** , to stop the active SnapMirror replication to the destination volume **cluster2://vs2.example.com/dept\_eng\_dp\_mirror1** , type the following command:

```
cluster2::> snapmirror abort -destination-path  
cluster2://vs2.example.com/dept_eng_dp_mirror1
```

To stop the active SnapMirror replication to the destination Vserver **dvs1.example.com** , type the following command:

```
cluster2::> snapmirror abort -destination-path  
dvs1.example.com:
```

# snapmirror break

## Make SnapMirror destination writable

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **snapmirror break** command breaks a SnapMirror relationship between a source and destination endpoint of a data protection mirror. The destination endpoint can be a Vserver, volume or SolidFire endpoint. When Data ONTAP breaks the relationship, if the endpoint is a volume or SolidFire endpoint, the destination is made read/write and can diverge from the source volume, client redirection is turned off on the destination, the restart checkpoint is cleared, and the clients can see the latest Snapshot copy. If the endpoint is a Vserver, the subtype of the destination Vserver is changed to **default** , volumes in the destination Vserver are made read/write and the clients can now access the Vserver namespace for modifications. For SolidFire destination endpoints, the **snapmirror break** command is only supported if the endpoint is in a SnapMirror relationship.

Subsequent manual or scheduled SnapMirror updates to the broken relationship will fail until the SnapMirror relationship is reestablished using the [snapmirror resync](#) command.

This command applies to data protection mirrors. For vault relationships, this command is only intended for use when preparing for a Data ONTAP revert operation (see the **-delete-snapshots** parameter in advanced privilege level). This command is not intended for use with load-sharing mirrors.

For relationships with a policy of type **strict-sync-mirror** or **sync-mirror** , the relationship must be **Quiesced** before running the **snapmirror break** command.

This command is supported for SnapMirror relationships with the field **"Relationship Capability"** showing as either **"8.2 and above"** or **"Pre 8.2"** in the output of the [snapmirror show](#) command.

The **snapmirror break** command must be used from the destination Vserver or cluster.

## Parameters

{ [-S, -source-path

{<[vserver:][volume]>|<[[cluster:]/vserver/]volume>|<hostip:/lun/name>|<hostip:/share/share-name>|<[vserver:]/cg/[cgname]>} - Source Path

This parameter specifies the source endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or the volume (volume). To support relationships with **"Relationship Capability"** of **"Pre 8.2"**, a format which also includes the name of the cluster (cluster) is provided. The **"Pre 8.2"** format cannot be used when operating in a Vserver context on relationships with **"Relationship Capability"** of **"8.2 and above"**. For SnapMirror relationships with an AltaVault source, the source endpoint is specified in the form **hostip:/share/share-name**. For SnapMirror relationships with a SolidFire source, the source endpoint is specified in the form **hostip:/lun/name**.

| [-source-cluster <Cluster name>] - Source Cluster

Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the **-source-vserver** and **-source-volume** parameters must also be specified. This parameter is only applicable for relationships with **"Relationship Capability"** of **"Pre 8.2"**. This parameter cannot be specified when operating in a Vserver context on relationships with **"Relationship Capability"** of **"8.2 and above"**.

[-source-vserver <vserver name>] - Source Vserver

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters **-source-volume** and for relationships with **"Relationship Capability"** of **"Pre 8.2"**, **-source-cluster** must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

[-source-volume <volume name>] - Source Volume }

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters **-source-vserver** and for relationships with **"Relationship Capability"** of **"Pre 8.2"**, **-source-cluster** must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

{ -destination-path

{<[vserver:][volume]>|<[[cluster:]/vserver/]volume>|<hostip:/lun/name>|<hostip:/share/share-name>|<[vserver:]/cg/[cgname]>} - Destination Path

This parameter specifies the destination endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with **"Relationship Capability"** of **"Pre 8.2"**, a format which also includes the name of the cluster (cluster) is provided. The **"Pre 8.2"** format cannot be used when operating in a Vserver context on relationships with **"Relationship Capability"** of **"8.2 and above"**. For SnapMirror relationships with AltaVault destinations, the destination endpoint is specified in the form **hostip:/share/share-name**. For relationships with SolidFire destinations, the destination endpoint is specified in the form **hostip:/lun/name**.

| [-destination-cluster <Cluster name>] - Destination Cluster

Specifies the destination cluster of the SnapMirror relationship. If this parameter is specified,

parameters **-destination-vserver** and **-destination-volume** must also be specified. This parameter is only applicable for relationships with **"Relationship Capability"** of **"Pre 8.2"** . This parameter cannot be specified when operating in a Vserver context on relationships with **"Relationship Capability"** of **"8.2 and above"** .

#### **-destination-vserver <vserver name> - Destination Vserver**

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters **-destination-volume** and for relationships with **"Relationship Capability"** of **"Pre 8.2"** , **-destination-cluster** must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

#### **-destination-volume <volume name> - Destination Volume }**

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameters **-destination-vserver** and for relationships with **"Relationship Capability"** of **"Pre 8.2"** , **-destination-cluster** must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

#### **[-f, -force <true>] - Force**

If this parameter is specified, the command proceeds without prompting for confirmation.

#### **[-w, -foreground <true>] - Foreground Process**

This specifies whether the operation runs as a foreground process. If this parameter is specified, the default setting is **true** (the operation runs in the foreground). When set to **true** , the command will not return until the process completes. This parameter is only applicable to relationships with **"Relationship Capability"** of **"Pre 8.2"** .

#### **[-delete-snapshots <true>] - Delete Snapshots for Revert**

Using this parameter causes break to delete Snapshot copies on a vault destination so that the system can be reverted. Note that the only Snapshot copies that will be deleted are those that were created with the current version of Data ONTAP. Any Snapshot copies that might be present created with a different version will not be deleted. This parameter is not supported for SnapLock Compliance destinations.

#### **[-s, -restore-destination-to-snapshot <text>] - Restore Destination to Snapshot Copy**

This optional parameter specifies the Snapshot copy to which the destination volume is restored after a successful break operation. If the parameter is not specified, the destination is restored to the latest Snapshot copy. This parameter is not supported for Vserver or FlexGroup relationships or SnapLock Compliance destinations.

#### **[-recover <true>] - Recover**

When a SnapMirror break operation fails on a FlexGroup relationship, a subset of the destination FlexGroup constituents could have been made writable and subsequently user data could have been written to these constituents. To recover from this failure, you can execute the **snapmirror break** command again specifying the **-recover** parameter. All constituents will be restored to the latest Snapshot copy, and any writes to the read-write constituents will be lost. This parameter is applicable only for SnapMirror relationships with FlexGroup endpoints.

## Examples

To stop the SnapMirror replication to the destination volume **vs2.example.com:dept\_eng\_dp\_mirror1** , type the following command:

```
vs2.example.com::> snapmirror break -destination-path  
vs2.example.com:dept_eng_dp_mirror1
```

For relationships with "**Relationship Capability**" of "**Pre 8.2**" , to stop the SnapMirror replication to the destination volume **cluster2://vs2.example.com/dept\_eng\_dp\_mirror1** , type the following command:

```
cluster2::> snapmirror break  
-destination-path cluster2://vs2.example.com/dept_eng_dp_mirror1
```

To stop replication to the destination Vserver **dvs1.example.com** of a Vserver SnapMirror relationship, type the following command:

```
cluster2::> snapmirror break -destination-path dvs1.example.com:
```

# snapmirror create

Create a new SnapMirror relationship

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **snapmirror create** command creates a SnapMirror relationship between a source and destination endpoint. You can use this command to create a data protection relationship, an extended data protection relationship, or a load-sharing relationship between FlexVol volumes. You can also use it to create a data protection relationship between Vservers.

You can also use the **snapmirror create** command to create an extended data protection relationship between FlexGroups. FlexGroups only support extended data protection relationships.

The source or destination of a FlexGroup SnapMirror relationship cannot be the source or destination of any non-FlexGroup SnapMirror relationship.

You can use the **snapmirror create** command to create a data protection relationship or an extended data protection relationship between SnapLock source and SnapLock destination endpoints.

The default relationship type is extended data protection (XDP), otherwise it is data protection (DP).

A SnapMirror relationship can also be created between a non-SnapLock source and a SnapLock destination to WORM-protect Snapshot copies. In this case, the relationship type is always set to extended data protection (XDP).

The **snapmirror create** command can be used to create an extended data protection (XDP) relationship between a Data ONTAP volume and a non-Data ONTAP endpoint that supports SnapMirror (AltaVault, Solidfire). AltaVault endpoints can only be used as destinations. SolidFire endpoints can be used as sources or destinations.

The **snapmirror create** command can be used to create a synchronous relationship between FlexVol volumes, which provides zero Recovery Point Objective (RPO) data protection. SnapMirror Synchronous supports two policy types, **sync-mirror** and **strict-sync-mirror**. Upon a permanent replication failure, the strict-sync-mirror variant restricts further client IO on the primary, whereas the sync-mirror variant does not.

The **snapmirror create** command can be used to create a SnapMirror Business Continuity (SMBC) relationship between Consistency Groups that have FlexVol volumes as items. This provides zero RPO and zero Recovery Time Objective (RTO) data protection, also known as transparent application failover, for SAN workloads. An SMBC relationship supports the **automated-failover** policy type and can only be created when the systems containing the source items and the destination items are running ONTAP 9.9.1 or later.

Before using this command to create a SnapMirror relationship between Vservers, you typically create a source and destination Vserver using the [vserver create](#) command. The source Vserver should be of **subtypedefault** and the destination Vserver of **subtypedp-destination**. Also, before creating the relationship between Vservers, you must setup Vserver peer by using the [vserver peer create](#) command between the source and destination Vservers. A Vserver relationship cannot be created between two Vservers within the same cluster. The root volume of the destination Vserver will be read-write and data from the source Vserver's root volume will not be replicated. Therefore there will be no volume level relationship created between the root volumes of the two Vservers.

After creating the relationship, the destination Vserver must be initialized by using the [snapmirror initialize](#) command.

Before using this command to create a volume SnapMirror relationship, you typically create a source and destination volume using the [volume create](#) command. The source volume should be in the online state and a read-write (RW) type. The destination volume should be in the online state and a data protection (DP) type. For FlexGroup SnapMirror relationships, the source and destination FlexGroups must be spread over the same number of aggregates as specified in the **-aggr-list** parameter with the same number of constituents per aggregate as specified in the **-aggr-list-multiplier** parameter of the [volume create](#) command.

When a FlexGroup SnapMirror relationship is created, normally hidden relationships are also created for the constituent volumes. These relationships can be seen by using the **-expand** parameter of the [snapmirror show](#) command. Source information for these relationships can be seen using the **-expand**

parameter of the [snapmirror list-destinations](#) command. Other SnapMirror commands are disabled for FlexGroup constituent relationships and FlexGroup constituent volumes.

If all systems involved are running Data ONTAP version 8.2 and later, a Vserver peering relationship must be set up using the [vserver peer create](#) command between the source and the destination Vservers to create a relationship between the source and destination volumes. To enable interoperability with Data ONTAP 8.1, if the source volume is on a storage system running clustered Data ONTAP 8.1, the cluster administrator can create a data protection relationship between the source and destination volumes without a Vserver peering relationship between the source and destination Vservers. These relationships are managed the same way as on Data ONTAP 8.1 and the **"Relationship Capability"** field, as shown in the output of the [snapmirror show](#) command, is set to **"Pre 8.2"**.

SnapMirror relationships, except load-sharing relationships, which are created between two volumes which are both on a storage system running Data ONTAP version 8.2 and later have the **"Relationship Capability"** field set to **"8.2 and above"**.

Load-sharing mirrors must be confined to a single Vserver; they are not allowed to span Vservers. Load-sharing relationships are created with the **"Relationship Capability"** field set to **"Pre 8.2"** even if both the source and destination volumes are on a storage system running Data ONTAP version 8.2 and later. There is no **"8.2 and above"** implementation for load-sharing relationships.

A set of load-sharing mirrors can have one or more destination volumes. You create separate SnapMirror relationships between the common source volume and each destination volume to create the set of load-sharing mirrors.

The source or destination of a load-sharing relationship cannot be the source or destination of any other SnapMirror relationship.

After creating the relationship, the destination volume can be initialized using the [snapmirror initialize](#) command. The destination volumes in a set of load-sharing mirrors are initialized using the [snapmirror initialize-ls-set](#) command.

The `snapmirror create` command must be used from the destination Vserver or cluster.

## Parameters

`{ -S, -source-path`

`{<[vserver:][volume]>|<[[cluster:]/vserver/]volume>|<hostip:/lun/name>|<hostip:/share/share-name>|<[vserver:]/cg/[cgname]>} - Source Path`

This parameter specifies the source endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or the volume (volume). To support relationships with **"Relationship Capability"** of **"Pre 8.2"**, a format which also includes the name of the cluster (cluster) is provided. The **"Pre 8.2"** format cannot be used when operating in a Vserver context on relationships with **"Relationship Capability"** of **"8.2 and above"**. For SnapMirror relationships with an AltaVault source, the source endpoint is specified in the form **hostip:/share/share-name**. For SnapMirror relationships with a SolidFire source, the

source endpoint is specified in the form **hostip:/lun/name** .

### **[ -source-cluster <Cluster name> ] - Source Cluster**

Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the **-source-vserver** and **-source-volume** parameters must also be specified. This parameter is only applicable for relationships with **"Relationship Capability"** of **"Pre 8.2"** . This parameter cannot be specified when operating in a Vserver context on relationships with **"Relationship Capability"** of **"8.2 and above"** .

### **-source-vserver <vserver name> - Source Vserver**

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters **-source-volume** and for relationships with **"Relationship Capability"** of **"Pre 8.2"** , **-source-cluster** must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

### **[ -source-volume <volume name> ] - Source Volume }**

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters **-source-vserver** and for relationships with **"Relationship Capability"** of **"Pre 8.2"** , **-source-cluster** must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

### **{ -destination-path**

**{<[vserver:][volume]>|<[[cluster:]/vserver/]volume>|<hostip:/lun/name>|<hostip:/share/share-name>|<[vserver:]/cg/[cgname]>} - Destination Path**

This parameter specifies the destination endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with **"Relationship Capability"** of **"Pre 8.2"** , a format which also includes the name of the cluster (cluster) is provided. The **"Pre 8.2"** format cannot be used when operating in a Vserver context on relationships with **"Relationship Capability"** of **"8.2 and above"** . For SnapMirror relationships with AltaVault destinations, the destination endpoint is specified in the form **hostip:/share/share-name** . For relationships with SolidFire destinations, the destination endpoint is specified in the form **hostip:/lun/name** .

### **[ -destination-cluster <Cluster name> ] - Destination Cluster**

Specifies the destination cluster of the SnapMirror relationship. If this parameter is specified, parameters **-destination-vserver** and **-destination-volume** must also be specified. This parameter is only applicable for relationships with **"Relationship Capability"** of **"Pre 8.2"** . This parameter cannot be specified when operating in a Vserver context on relationships with **"Relationship Capability"** of **"8.2 and above"** .

### **-destination-vserver <vserver name> - Destination Vserver**

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters **-destination-volume** and for relationships with **"Relationship Capability"** of **"Pre 8.2"** , **-destination-cluster** must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

**-destination-volume <volume name> - Destination Volume }**

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameters **-destination-vserver** and for relationships with "**Relationship Capability**" of "**Pre 8.2**" , **-destination-cluster** must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

**[-type <snapmirrorType>] - Relationship Type**

This parameter specifies the type of SnapMirror relationship that will be created. You can create a data protection (DP) relationship (deprecated), an extended data protection (XDP) relationship or a load-sharing (LS) relationship. The default value is XDP for all relationships except for Vserver DR relationships. FlexGroup volumes and non-Data ONTAP endpoints support only XDP relationships. For FlexVol volume relationships, when DP is specified as the type, an XDP relationship will be created unless a relationship of type DP in the opposite direction already exists. In that case the new relationship will be of type DP.

**[-vserver <vserver name>] - Managing Vserver**

If this optional parameter is specified, it designates the managing Vserver. The managing Vserver is authorized to use SnapMirror commands to manage the SnapMirror relationship. The **-vserver** parameter is currently a reserved parameter.

**[-schedule <text>] - SnapMirror Schedule**

This optional parameter designates the name of the schedule which is used to update the SnapMirror relationship. If you do not designate a schedule, updates are not scheduled, so you must update the SnapMirror relationship manually using the [snapmirror update](#) command or, in the case of a set of load-sharing mirrors, using the [snapmirror update-ls-set](#) command.

You define and name a schedule using the [job schedule cron create](#) command.

**[-policy <sm\_policy>] - SnapMirror Policy**

This optional parameter designates the name of the SnapMirror policy which is associated with the SnapMirror relationship. For FlexVol volume relationships, the default policy when the data protection (DP) type is specified is **MirrorAllSnapshots** and the default policy when no type is specified or when the extended data protection (XDP) type is specified is **MirrorAndVault** . For FlexGroup volume relationships, the **MirrorAndVault** policy is applied. For SnapMirror relationships between SnapLock volumes, if no policy is specified the default policy **MirrorAllSnapshots** is applied. For relationships with a SolidFire endpoint, there is no default policy. For these relationships a policy as described below must be specified. This parameter is not applicable to relationships with "**Relationship Capability**" of "**Pre 8.2**" .

In clustered Data ONTAP 8.2 data protection (DP) relationships were used for mirroring, while extended data protection (XDP) relationships were used for vaulting. In clustered Data ONTAP 8.3 extended data protection (XDP) relationships support two more use cases, mirroring and unified mirror-vault. The exact behavior of an extended data protection (XDP) relationship is governed by the **snapmirror policy** associated with that relationship. In clustered Data ONTAP 8.3 the **snapmirror policy** has a new field **type** to indicate how the relationships with that policy will behave. The supported types are **async-mirror** (mirroring), **vault** (vaulting) and **mirror-vault** (unified mirroring and vault). For XDP relationships between a Data ONTAP source volume and an

AltaVault destination endpoint, only policies of type **vault** are supported. For XDP relationships between a Data ONTAP source volume and a SolidFire destination endpoint, only policies of type **async-mirror** without an **all\_source\_snapshots** rule are supported. For XDP relationships between a SolidFire source endpoint and a Data ONTAP destination volume, only policies of type **async-mirror** without an **all\_source\_snapshots** rule, and policies of type **mirror-vault** are supported. SnapMirror policies of type **async-mirror** associated with FlexVol volume relationships when relationship type DP is specified or when no relationship type is specified, must include the label **all\_source\_snapshots**. Refer to the man page for the [snapmirror policy create](#) command for more information.

You define and name a policy using the [snapmirror policy create](#) command.

#### **[-tries <unsigned32\_or\_unlimited>] - Tries Limit**

This optional parameter specifies the maximum number of times to attempt each manual or scheduled transfer for a SnapMirror relationship. The default is eight times. The **-tries** parameter can be set to **0** to disable manual and scheduled updates for the SnapMirror relationship. This parameter is only applicable to relationships with "**Relationship Capability**" of "**Pre 8.2**". For relationships with "**8.2 and above**" capability, the tries limit is controlled by the value of tries in the SnapMirror policy that is associated with the relationship.

#### **[-k, -throttle <throttleType>] - Throttle (KB/sec)**

This optional parameter limits the network bandwidth used for transfers. It configures for the relationship the maximum rate (in Kbytes/sec) at which data can be transferred. If no throttle is configured, by default the SnapMirror relationship fully utilizes the network bandwidth available. You can also configure the relationship to fully use the network bandwidth available by explicitly setting the throttle to **unlimited** or **0**. The minimum effective throttle value is four Kbytes/sec, so if you specify a throttle value between **1** and **4**, it will be treated as **4**. For FlexGroup volume relationships, the throttle value is applied individually to each constituent relationship. The **-throttle** parameter does not affect load-sharing mirrors and other SnapMirror relationships with "**Relationship Capability**" of "**Pre 8.2**" confined to a single cluster.

#### **[-cg-item-mappings {<source volume>:@<destination volume>|<source item path>:@<destination item path>}] - Consistency Group Item Mappings**

This optional parameter specifies a list of the consistency group (CG) item mappings. It is considered only if the supplied source and destination path values denote valid CG paths. For CG level relationships, this parameter must be specified. The value for this parameter must contain mappings of one or more pairs of constituent source and destination volumes of the form **srcvol1:@dstvol1,...**

#### **[-identity-preserve {true|false}] - Identity Preserve Vserver DR**

Specifies whether or not the identity of the source Vserver is replicated to the destination Vserver of the Vserver SnapMirror relationship that will be created. If this parameter is set to true, the source Vserver's configuration will additionally be replicated to the destination. If the parameter is set to false, then only the source Vserver's volumes and RBAC configuration are replicated to the destination. This parameter is applicable only for SnapMirror relationships with Vserver endpoints. The default value is false.

## **[`-is-auto-expand-enabled {true|false}`] - Is Auto Expand Enabled**

This optional parameter specifies whether or not a FlexGroup SnapMirror relationship and its destination FlexGroup volume should be auto-expanded if the source FlexGroup volume is expanded. This parameter is supported only for FlexGroup SnapMirror relationships. The default value is true.

## Examples

To create an extended data protection relationship between the source endpoint **vs1.example.com:dept\_eng**, and the destination endpoint **vs2.example.com:dept\_eng\_dp\_mirror2**, with the default policy of **MirrorAndVault**, type the following command:

```
vs2.example.com:;> snapmirror create -destination-path
vs2.example.com:dept_eng_dp_mirror2 -source-path
vs1.example.com:dept_eng
```

To create an extended data protection relationship between the source FlexGroup **vs1.example.com:fg\_src** and the destination FlexGroup **vs2.example.com:fg\_dst**, with the default policy of **MirrorAndVault**, type the following command:

```
vs2.example.com:;> snapmirror create -destination-path
vs2.example.com:fg_dst -source-path
vs1.example.com:fg_src
```

To create a synchronous SnapMirror relationship between the source Flexvol **vs1.example.com:vol\_log**, and the destination Flexvol **vs2.example.com:vol\_log\_sync\_dp** when the source cluster is running ONTAP 9.5 or above, type the following command:

```
vs2.example.com:;> snapmirror create -destination-path
vs2.example.com:vol_log_sync_dp -source-path
vs1.example.com:vol_log -policy Sync
```

To create a strict synchronous SnapMirror relationship between the source Flexvol **vs1.example.com:vol\_log**, and the destination Flexvol **vs2.example.com:vol\_log\_sync\_dp** when the source cluster is running ONTAP 9.5 or above, type the following command:

```
vs2.example.com:;> snapmirror create -destination-path
vs2.example.com:vol_log_sync_dp -source-path
vs1.example.com:vol_log -policy StrictSync
```

To create a data protection mirror between the source endpoint **cluster1://vs1.example.com/dept\_eng**, and the destination endpoint **cluster2://vs2.example.com/dept\_eng\_dp\_mirror2** when the source cluster is running Data ONTAP 8.1 software, type the following command:

```
cluster2::> snapmirror create -destination-path
            cluster2://vs2.example.com/dept_eng_dp_mirror2 -source-path
            cluster1://vs1.example.com/dept_eng
            -type DP
```

To create a load-sharing mirror between the source endpoint **cluster1://vs1.example.com/vs1\_root** which is a Vserver root volume, and the destination endpoint **cluster1://vs1.example.com/vs1\_root\_ls1** with the schedule named **5min** used to update the relationship, type the following command:

```
cluster1::> snapmirror create
            -destination-path cluster1://vs1.example.com/vs1_root_ls1
            -source-path      cluster1://vs1.example.com/vs1_root -type LS -schedule 5min
```

To create a SnapMirror relationship between the source Vserver **vs1.example.com**, and the destination Vserver **dvs1.example.com** with the schedule named **hourly** used to update the relationship, type the following command:

```
cluster2::> snapmirror create
            -destination-path dvs1.example.com:
            -source-path vs1.example.com:
            -schedule hourly
```

To create an extended data protection (XDP) relationship between the Data ONTAP source endpoint **vs1.example.com:data\_ontap\_vol**, and the AltaVault destination endpoint **10.0.0.11:/share/share1**, type the following command:

```
vs1.example.com::> snapmirror create -destination-path
            10.0.0.11:/share/share1 -source-path
            vs1.example.com:data_ontap_vol
            -type XDP
```

To create an extended data protection (XDP) relationship between the SolidFire source endpoint **10.0.0.12:/lun/0001**, and the Data ONTAP destination endpoint **vs2.example.com:data\_ontap\_vol2**, type the following command:

```
vs2.example.com::> snapmirror create -source-path
            10.0.0.12:/lun/0001 -destination-path
            vs2.example.com:data_ontap_vol2
            -type XDP -policy MirrorLatest
```

To create an SMBC relationship with the following attributes:

- It is between the source Consistency Group **cg\_src** in Vserver **vs1.example.com**, and the

destination Consistency Group **cg\_dst** in Vserver **vs2.example.com** .

- It has item mappings between volumes **srcvol1** and **srcvol2** and volumes **dstvol1** and **dstvol2** .
- It uses the default policy named **AutomatedFailOver** that has a policy type of **automated-failover** .

Type the following command from the destination cluster:

```
destination::> snapmirror create -destination-path  
vs2.example.com:/cg/cg_dst -source-path  
vs1.example.com:/cg/cg_src  
-cg-item-mappings srcvol1:@dstvol1,srcvol2:@dstvol2
```

# snapmirror delete

Delete a SnapMirror relationship

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **snapmirror delete** command removes the SnapMirror relationship between a source endpoint and a destination endpoint. The destination endpoint can be a Vserver, a volume, a Consistency Group with FlexVol volumes as constituents, or a non-Data ONTAP endpoint. The Vservers, volumes, FlexVol volumes of the Consistency Group and non-Data ONTAP destinations are not destroyed and Snapshot copies on the volumes are not removed.

For relationships with SolidFire endpoints, the SnapMirror source commands [snapmirror release](#) and

**snapmirror list-destinations** are not supported. Therefore, Snapshot copies that are locked by SnapMirror on the source container cannot be cleaned up using the **snapmirror release** command. If the source container is a Data ONTAP volume, in order to reclaim space captured in the base Snapshot copy on the volume, issue a **snapshot delete** command specifying the **-ignore-owners** parameter in diag privilege level. To reclaim space captured in a Snapshot copy locked by SnapMirror on a SolidFire system, refer to SolidFire documentation.

The **snapmirror delete** command fails if a SnapMirror transfer for the SnapMirror relationship is in progress for relationships with **"Relationship Capability"** of **"Pre 8.2"** . For relationships with **"8.2 and above"** capability the delete will succeed even if a transfer is in progress and the transfer will ultimately stop.

A set of load-sharing mirrors can contain multiple destination volumes, each destination volume having a separate SnapMirror relationship with the common source volume. When used on one of the SnapMirror relationships from the set of load-sharing mirrors, the **snapmirror delete** command deletes the specified SnapMirror relationship from the set of load-sharing mirrors.

The **snapmirror delete** command preserves the read-write or read-only attributes of the volumes of a SnapMirror relationship after the relationship is deleted. Therefore, a read-write volume that was the source of a SnapMirror relationship retains its read-write attributes, and a data protection volume or a load-sharing volume that was a destination of a SnapMirror relationship retains its read-only attributes. Similarly, the **subtype** attribute of source and destination Vservers is not modified when a Vserver SnapMirror relationship is deleted.

When a SnapMirror relationship from a set of load-sharing mirrors is deleted, the destination volume becomes a data protection volume and retains the read-only attributes of a data protection volume.

For relationships with a policy of type **strict-sync-mirror** or **sync-mirror** , the relationship must be **Quiesced** before it can be deleted.

This command is supported for SnapMirror relationships with the field **"Relationship Capability"** showing as either **"8.2 and above"** or **"Pre 8.2"** in the output of the **snapmirror show** command.

For relationships with **"Relationship Capability"** of **"8.2 and above"** , the **snapmirror delete** command must be used from the destination Vserver or cluster. The SnapMirror relationship information is deleted from the destination Vserver, but no cleanup or deletion is performed on the source Vserver. The **snapmirror release** command must be issued on the source Vserver to delete the source relationship information.

For relationships with **"Relationship Capability"** of **"Pre 8.2"** , you can use this command from the source or from the destination cluster. When used from the destination cluster, the SnapMirror relationship information on the source and destination clusters is deleted. When used from the source cluster, only the SnapMirror relationship information on the source cluster is deleted.

## Parameters

**{ [-S, -source-path**

**{<[vserver:][volume]>|<[[cluster:]/vserver/]volume>|<hostip:/lun/name>|<hostip:/share/share-name>|<[vserver:]/cg/[cgname]>}** - Source Path

This parameter specifies the source endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or the volume (volume). To support relationships with **"Relationship Capability"** of **"Pre 8.2"**, a format which also includes the name of the cluster (cluster) is provided. The **"Pre 8.2"** format cannot be used when operating in a Vserver context on relationships with **"Relationship Capability"** of **"8.2 and above"**. For SnapMirror relationships with an AltaVault source, the source endpoint is specified in the form **hostip:/share/share-name**. For SnapMirror relationships with a SolidFire source, the source endpoint is specified in the form **hostip:/lun/name**.

**[-source-cluster <Cluster name>] - Source Cluster**

Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the **-source-vserver** and **-source-volume** parameters must also be specified. This parameter is only applicable for relationships with **"Relationship Capability"** of **"Pre 8.2"**. This parameter cannot be specified when operating in a Vserver context on relationships with **"Relationship Capability"** of **"8.2 and above"**.

**[-source-vserver <vserver name>] - Source Vserver**

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters **-source-volume** and for relationships with **"Relationship Capability"** of **"Pre 8.2"**, **-source-cluster** must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

**[-source-volume <volume name>] - Source Volume }**

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters **-source-vserver** and for relationships with **"Relationship Capability"** of **"Pre 8.2"**, **-source-cluster** must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

**{ -destination-path**

**{<[vserver:][volume]>|<[[cluster:]/vserver/]volume>|<hostip:/lun/name>|<hostip:/share/share-name>|<[vserver:]/cg/[cgname]>}** - Destination Path

This parameter specifies the destination endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with **"Relationship Capability"** of **"Pre 8.2"**, a format which also includes the name of the cluster (cluster) is provided. The **"Pre 8.2"** format cannot be used when operating in a Vserver context on relationships with **"Relationship Capability"** of **"8.2 and above"**. For SnapMirror relationships with AltaVault destinations, the destination endpoint is specified in the form **hostip:/share/share-name**. For relationships with SolidFire destinations, the destination endpoint is specified in the form **hostip:/lun/name**.

**[-destination-cluster <Cluster name>] - Destination Cluster**

Specifies the destination cluster of the SnapMirror relationship. If this parameter is specified, parameters **-destination-vserver** and **-destination-volume** must also be specified. This parameter is only applicable for relationships with **"Relationship Capability"** of **"Pre 8.2"**. This parameter

cannot be specified when operating in a Vserver context on relationships with **"Relationship Capability"** of **"8.2 and above"**.

#### **-destination-vserver <vserver name> - Destination Vserver**

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters **-destination-volume** and for relationships with **"Relationship Capability"** of **"Pre 8.2"**, **-destination-cluster** must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

#### **-destination-volume <volume name> - Destination Volume }**

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameters **-destination-vserver** and for relationships with **"Relationship Capability"** of **"Pre 8.2"**, **-destination-cluster** must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

#### **[-f, -force <true>] - Force**

If specified, the delete proceeds even if it cannot clean up all artifacts of the relationship.

#### **[-w, -foreground <true>] - Foreground Process**

This specifies whether the operation runs as a foreground process. If this parameter is specified, the default setting is **true** (the operation runs in the foreground). When set to **true**, the command will not return until the process completes. This parameter is only applicable to relationships with **"Relationship Capability"** of **"Pre 8.2"**.

## Examples

To delete the SnapMirror relationship with the destination endpoint **vs2.example.com:dept\_eng\_dp\_mirror4**, type the following command:

```
vs2.example.com::> snapmirror delete -destination-path
vs2.example.com:dept_eng_dp_mirror4
```

For relationships with **"Relationship Capability"** of **"Pre 8.2"**, to delete the SnapMirror relationship with the destination endpoint **cluster2://vs2.example.com/dept\_eng\_dp\_mirror4**, type the following command:

```
cluster2::> snapmirror delete -destination-path
cluster2://vs2.example.com/dept_eng_dp_mirror4
```

To delete the SnapMirror relationship with destination endpoint **dvs1.example.com:**, type the following command:

```
cluster2::> snapmirror delete -destination-path
dvs1.example.com:
```

To delete the SnapMirror Business Continuity (SMBC) relationship with the destination Consistency Group **cg\_dst** in Vserver **vs2.example.com**, type the following command from the destination cluster:

```
destination::> snapmirror delete -destination-path  
vs2.example.com:/cg/cg_dst
```

# snapmirror initialize-ls-set

Start a baseline load-sharing set transfer

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **snapmirror initialize-ls-set** command initializes and updates a set of load-sharing mirrors. This command is usually used after the [snapmirror create](#) command is used to create a SnapMirror relationship for each of the destination volumes in the set of load-sharing mirrors. The initial transfers to empty load-sharing mirrors are baseline transfers done in parallel. During a baseline transfer Data ONTAP takes a Snapshot copy on the source volume to capture the current image of the source volume and transfers all of the Snapshot copies on the source volume to each of the destination volumes.

After the **snapmirror initialize-ls-set** command successfully completes, the last Snapshot copy transferred is made the exported Snapshot copy on the destination volumes.

The parameter that identifies the set of load-sharing mirrors is the source volume. Data and Snapshot copies are transferred from the source volume to all up-to-date destination volumes in the set of load-sharing mirrors.

Use the [snapmirror initialize](#) command to add and initialize a new destination volume to an existing set of load-sharing mirrors.

Even if the load-sharing set only has one mirror, you still need to use the **snapmirror initialize-ls-set** command to initialize the set. The [snapmirror initialize](#) command can only be used to initialize a new destination volume, if the load-sharing set has already been initialized.

This command is only supported for SnapMirror relationships with the field **"Relationship**

**Capability**" showing as **"Pre 8.2"** in the output of the `snapmirror show` command.

## Parameters

**{ -S, -source-path**

**{<[vserver:][volume]>|<[[cluster:]]//vserver/]volume>|<hostip:/lun/name>|<hostip:/share/share-name>|<[vserver:]/cg/[cgname]>} - Source Path**

This parameter specifies the source endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or the volume (volume). To support relationships with **"Relationship Capability"** of **"Pre 8.2"**, a format which also includes the name of the cluster (cluster) is provided. The **"Pre 8.2"** format cannot be used when operating in a Vserver context on relationships with **"Relationship Capability"** of **"8.2 and above"**. For SnapMirror relationships with an AltaVault source, the source endpoint is specified in the form **hostip:/share/share-name**. For SnapMirror relationships with a SolidFire source, the source endpoint is specified in the form **hostip:/lun/name**.

**[-source-cluster <Cluster name>] - Source Cluster**

Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the **-source-vserver** and **-source-volume** parameters must also be specified. This parameter is only applicable for relationships with **"Relationship Capability"** of **"Pre 8.2"**. This parameter cannot be specified when operating in a Vserver context on relationships with **"Relationship Capability"** of **"8.2 and above"**.

**-source-vserver <vserver name> - Source Vserver**

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters **-source-volume** and for relationships with **"Relationship Capability"** of **"Pre 8.2"**, **-source-cluster** must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

**-source-volume <volume name> - Source Volume }**

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters **-source-vserver** and for relationships with **"Relationship Capability"** of **"Pre 8.2"**, **-source-cluster** must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

**[-w, -foreground <>true>] - Foreground Process**

This specifies whether the operation runs as a foreground process. If this parameter is specified, the default setting is **true** (the operation runs in the foreground). When set to **true**, the command will not return until the process completes. This parameter is only applicable to relationships with **"Relationship Capability"** of **"Pre 8.2"**.

## Examples

To initialize the group of load-sharing mirrors for the source endpoint `//vs1.example.com/vs1_root`, type the following command:

```
cluster1::> snapmirror initialize-ls-set -source-path  
//vs1.example.com/vs1_root
```

- [snapmirror initialize](#)
- [snapmirror show](#)

# snapmirror initialize

Start a baseline transfer

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **snapmirror initialize** command initializes the destination Vserver, volume or a non-Data ONTAP endpoint of a SnapMirror relationship. The command behaves differently between data protection (DP), extended data protection (XDP) and load-sharing (LS) relationships.

If you specify a **sync-mirror** or **strict-sync-mirror** type policy, the **snapmirror initialize** command creates and initializes a synchronous relationship and brings it InSync, providing zero RPO data protection.

If you are initializing a relationship with a policy of type **automated-failover** the **snapmirror initialize** command initializes a SnapMirror Business Continuity (SMBC) relationship and brings the status to InSync, providing zero RPO and zero RTO data protection.

SMBC is only supported for SAN. As a result, NAS access is not supported on SMBC volumes and SMBC initialization is not supported on volumes with NAS access.

For data protection (DP) and extended data protection (XDP) relationships, the **snapmirror initialize** command initializes the destination volume.

For load-sharing (LS) relationships, the **snapmirror initialize** command initializes a new load-sharing mirror in an existing set of load-sharing mirrors. If the command finishes before the start of a scheduled or manual transfer of the set of load-sharing mirrors, the load-sharing mirror is up to date with the set of load-sharing mirrors; otherwise, the load-sharing mirror will be brought up to date at the next scheduled or manual transfer of the set of load-sharing mirrors.

The initial transfer to an empty destination volume is called a baseline transfer. During a baseline transfer for a data protection (DP) or extended data protection (XDP) relationship, the **snapmirror initialize** command takes a Snapshot copy on the source volume to capture the current image of

the source volume. For data protection relationships, the `snapmirror initialize` command transfers all of the Snapshot copies up to and including the Snapshot copy created by it from the source volume to the destination volume. For extended data protection (XDP) relationships, the `snapmirror initialize` command behavior depends on the `snapmirror policy` associated with the relationship. If the policy type is `async-mirror` then depending on the rules in the policy it can transfer either all the Snapshot copies up to and including the Snapshot copy created by it or only the Snapshot copy created by it from the source volume to the destination volume. For extended data protection (XDP) relationships with policy type `vault` or `mirror-vault` the `snapmirror initialize` transfers only the Snapshot copy created by it.

After the `snapmirror initialize` command successfully completes, the last Snapshot copy transferred is made the exported Snapshot copy on the destination volume.

You can use the `snapmirror initialize` command to initialize a specific load-sharing mirror that is new to the set of load-sharing mirrors. An initialize of the new load-sharing mirror should bring it up to date with the other up-to-date destination volumes in the set of load-sharing mirrors.

Using the `snapmirror initialize` command to initialize a set of load-sharing mirrors will not work. Use the `snapmirror initialize-ls-set` command to initialize a set of load-sharing mirrors.

If a SnapMirror relationship does not already exist, that is, the relationship was not created using the `snapmirror create` command, the `snapmirror initialize` command will implicitly create the SnapMirror relationship, with the same behaviors as described for the `snapmirror create` command before initializing the relationship. This implicit create feature is not supported for Vservers.

This command is supported for SnapMirror relationships with the field **"Relationship Capability"** showing as either **"8.2 and above"** or **"Pre 8.2"** in the output of the `snapmirror show` command.

For relationships with **"Relationship Capability"** of **"8.2 and above"**, you can track the progress of the operation using the `snapmirror show` command.

For relationships with **"Relationship Capability"** of **"Pre 8.2"**, a job will be spawned to operate on the SnapMirror relationship, and the job id will be shown in the command output. The progress of the job can be tracked using the `job show` and `job history show` commands.

The `snapmirror initialize` command must be used from the destination Vserver or cluster.

## Parameters

```
{ [-S, -source-path
{<[vserver:][volume]>|<[[cluster:]]//vserver/]volume>|<hostip:/lun/name>|<hostip:/share/share-
name>|<[vserver:]/cg/[cgname]>}] - Source Path
```

This parameter specifies the source endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or the volume (volume). To support relationships with **"Relationship Capability"** of **"Pre 8.2"**, a format which also includes the name of the cluster (cluster) is provided. The **"Pre 8.2"** format cannot be used when operating in a Vserver context on relationships with **"Relationship Capability"** of **"8.2 and**

**above** . For SnapMirror relationships with an AltaVault source, the source endpoint is specified in the form **hostip:/share/share-name** . For SnapMirror relationships with a SolidFire source, the source endpoint is specified in the form **hostip:/lun/name** .

#### **[ -source-cluster <cluster name> ] - Source Cluster**

Specifies the source cluster of the SnapMirror relationship. If this parameter is specified, the **-source-vserver** and **-source-volume** parameters must also be specified. This parameter is only applicable for relationships with **"Relationship Capability"** of **"Pre 8.2"** . This parameter cannot be specified when operating in a Vserver context on relationships with **"Relationship Capability"** of **"8.2 and above"** .

#### **[ -source-vserver <vserver name> ] - Source Vserver**

Specifies the source Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters **-source-volume** and for relationships with **"Relationship Capability"** of **"Pre 8.2"** , **-source-cluster** must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

#### **[ -source-volume <volume name> ] - Source Volume }**

Specifies the source volume of the SnapMirror relationship. If this parameter is specified, parameters **-source-vserver** and for relationships with **"Relationship Capability"** of **"Pre 8.2"** , **-source-cluster** must also be specified. This parameter is not supported for relationships with non-Data ONTAP source endpoints.

#### **{ -destination-path**

**{<[vserver:][volume]>|<[[cluster:]/vserver/]volume>|<hostip:/lun/name>|<hostip:/share/share-name>|<[vserver:]/cg/[cgname]>} - Destination Path**

This parameter specifies the destination endpoint of the SnapMirror relationship in one of four path formats. The normal format includes the names of the Vserver (vserver) and/or volume (volume). To support relationships with **"Relationship Capability"** of **"Pre 8.2"** , a format which also includes the name of the cluster (cluster) is provided. The **"Pre 8.2"** format cannot be used when operating in a Vserver context on relationships with **"Relationship Capability"** of **"8.2 and above"** . For SnapMirror relationships with AltaVault destinations, the destination endpoint is specified in the form **hostip:/share/share-name** . For relationships with SolidFire destinations, the destination endpoint is specified in the form **hostip:/lun/name** .

#### **[ -destination-cluster <cluster name> ] - Destination Cluster**

Specifies the destination cluster of the SnapMirror relationship. If this parameter is specified, parameters **-destination-vserver** and **-destination-volume** must also be specified. This parameter is only applicable for relationships with **"Relationship Capability"** of **"Pre 8.2"** . This parameter cannot be specified when operating in a Vserver context on relationships with **"Relationship Capability"** of **"8.2 and above"** .

#### **-destination-vserver <vserver name> - Destination Vserver**

Specifies the destination Vserver of the SnapMirror relationship. For relationships with volumes as endpoints, if this parameter is specified, parameters **-destination-volume** and for relationships with **"Relationship Capability"** of **"Pre 8.2"** , **-destination-cluster** must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

**-destination-volume <volume name> - Destination Volume }**

Specifies the destination volume of the SnapMirror relationship. If this parameter is specified, parameters **-destination-vserver** and for relationships with **"Relationship Capability"** of **"Pre 8.2"** , **-destination-cluster** must also be specified. This parameter is not supported for relationships with non-Data ONTAP destination endpoints.

**[-s, -source-snapshot <text>] - Source Snapshot**

This optional parameter specifies the Snapshot copy that **snapmirror initialize** will use for the baseline transfer. For data protection (DP) relationships, the baseline transfer will include all of the Snapshot copies up to and including the specified Snapshot copy. For extended data protection (XDP) relationships, the **snapmirror initialize** command behavior depends on the **snapmirror policy** associated with the relationship. If the policy type is **async-mirror** then depending on the rules in the policy it can transfer either all the Snapshot copies up to and including the specified Snapshot copy or only the specified Snapshot copy from the source volume to the destination volume. For extended data protection (XDP) relationships with policy type **vault** or **mirror-vault** the **snapmirror initialize** transfers only the specified Snapshot copy. This parameter is not supported for SnapMirror Synchronous relationships and relationships with **"Relationship Capability"** of **"Pre 8.2"** .

**[-type <snapmirrorType>] - Snapmirror Relationship Type**

Specifies the type of SnapMirror relationship if a relationship is implicitly created. This parameter is the same as the one used in the [snapmirror create](#) command.

**[-policy <sm\_policy>] - SnapMirror Policy**

This optional parameter designates the name of the SnapMirror policy which is associated with the SnapMirror relationship. If you do not designate a policy, the current policy will be retained. This parameter is not applicable to relationships with **"Relationship Capability"** of **"Pre 8.2"** .

You define and name a policy using the [snapmirror policy create](#) command.

**[-k, -throttle <throttleType>] - Throttle (KB/sec)**

This optional parameter limits the network bandwidth used for the initialize transfer. It sets the maximum rate (in Kbytes/sec) at which data can be transferred during the operation. If this parameter is not specified, the throttle value configured for the relationship with the [snapmirror create](#) or [snapmirror modify](#) command will be used. To fully use the network bandwidth available, set the throttle value to **unlimited** or **0** . The minimum throttle value is four Kbytes/sec, so if you specify a throttle value between **1** and **4** , it will be treated as if you specified **4** . For FlexGroup relationships, the throttle value is applied individually to each constituent relationship. For SnapMirror Synchronous relationships the throttle value is applicable only for asynchronous transfers performed as part of user-initiated operations. The **-throttle** parameter does not affect load-sharing transfers and transfers for other relationships with **"Relationship Capability"** of **"Pre 8.2"** confined to a single cluster.

**[-transfer-priority {low|normal}] - Transfer Priority**

This optional parameter specifies the priority at which the transfer runs. The default value for this parameter is the value in the SnapMirror policy associated with this relationship. This parameter is not applicable to relationships with a **"Relationship Capability"** of **"Pre 8.2"** .

**[-cg-item-mappings {<source volume>:@<destination volume>|<source item path>:@<destination item path>}] - Consistency Group Item Mappings**

This optional parameter specifies a list of the consistency group (CG) item mappings. It is considered only if the supplied source and destination path values denote valid CG paths. For CG level relationships, this parameter must be specified. The value for this parameter must contain mappings of one or more pairs of constituent source and destination volumes of the form **srcvol1:dstvol1,...** .

**[-is-auto-expand-enabled {true|false}] - Is Auto Expand Enabled**

This optional parameter specifies whether or not a FlexGroup SnapMirror relationship and its destination FlexGroup should be auto-expanded if the source FlexGroup is expanded. This parameter is supported only for FlexGroup SnapMirror relationships. If this initialize is creating a new Snapmirror relationship, the default value is true. If it is not creating a new relationship, if a value is specified, it must match the current value for the existing relationship. If the parameter is not specified the existing value will be retained.

**[-w, -foreground <true>] - Foreground Process**

This specifies whether the operation runs as a foreground process. If this parameter is specified, the default setting is **true** (the operation runs in the foreground). When set to **true** , the command will not return until the process completes. This parameter is only applicable to relationships with **"Relationship Capability"** of **"Pre 8.2"** .

## Examples

To start the initial transfer for the SnapMirror relationship with the destination endpoint **vs2.example.com:dept\_eng\_dp\_mirror2** after the relationship has been created with the [snapmirror create](#) command, type the following command:

```
vs2.example.com::> snapmirror initialize -destination-path  
vs2.example.com:dept_eng_dp_mirror2
```

For relationships with **"Relationship Capability"** of **"Pre 8.2"** , to start the initial transfer for the SnapMirror relationship with the destination endpoint **cluster2://vs2.example.com/dept\_eng\_dp\_mirror2** after the relationship has been created with the [snapmirror create](#) command, type the following command:

```
cluster2::> snapmirror initialize -destination-path  
cluster2://vs2.example.com/dept_eng_dp_mirror2
```

To create a data protection mirror relationship between the source endpoint **vs1.example.com:dept\_mkt** , and the destination endpoint **vs2.example.com:dept\_mkt\_dp\_mirror** , and start the initial transfer, type the following command:

```
vs2.example.com::> snapmirror initialize -destination-path  
vs.example.com2:dept_mkt_dp_mirror
```

```
-source-path vs1.example.com:dept_mkt
```

To create a data protection mirror relationship between the source endpoint **cluster1://vs1.example.com/dept\_mkt** , and the destination endpoint **cluster2://vs2.example.com/dep\_mkt\_dp\_mirror** , and start the initial transfer when the source cluster is running Data ONTAP 8.1 software, type the following command:

```
cluster2::> snapmirror initialize -destination-path
cluster2://vs2.example.com/dep_mkt_dp_mirror
-source-path cluster1://vs1.example.com/dept_mkt
```

To create an extended data protection (XDP) relationship between the Data ONTAP source endpoint **vs1.example.com:data\_ontap\_vol** , and the AltaVault destination endpoint **10.0.0.11:/share/share1** , and start the initial transfer, type the following command:

```
vs1.example.com::> snapmirror initialize -destination-path
10.0.0.11:/share/share1
-source-path vs1.example.com:data_ontap_vol -type XDP
```

To start the initial transfer for the Vserver SnapMirror relationship with destination endpoint **dvs1.example.com:** after the relationship was created with the [snapmirror create](#) command, type the following command:

```
cluster2::> snapmirror initialize -destination-path
dvs1.example.com:
```

To initialize the SnapMirror Synchronous relationship between FlexVols **vol\_log** and **vol\_log\_sync\_dp** and bring it to InSync, after it is created using the [snapmirror create](#) command, type the following command:

```
vs2.example.com::> snapmirror initialize -destination-path
vs2.example.com:vol_log_sync_dp
```

To create a strict SnapMirror Synchronous relationship between FlexVols **vol\_log** and **vol\_log\_sync\_dp** , to initialize it and bring it to InSync, type the following command:

```
vs2.example.com::> snapmirror initialize -destination-path
vs2.example.com:vol_log_sync_dp -source-path
vs1.example.com:vol_log -policy StrictSync
```

To create and initialize an SMBC relationship with the following attributes:

- It is between the source Consistency Group **cg\_src** in Vserver **vs1.example.com** , and the

destination Consistency Group **cg\_dst** in Vserver **vs2.example.com** .

- It has item mappings between volumes **srcvol1** and **srcvol2** and volumes **dstvol1** and **dstvol2** .
- It uses the default policy named **AutomatedFailOver** that has a policy type of **automated-failover** .

Type the following command from the destination cluster:

```
destination::> snapmirror initialize -destination-path
vs2.example.com:/cg/cg_dst -source-path
vs1.example.com:/cg/cg_src
-cg-item-mappings srcvol1:@dstvol1,srcvol2:@dstvol2
```

To initialize the previously created SMBC relationship, type the following command from the destination cluster:

```
destination::> snapmirror initialize -destination-path
vs2.example.com:/cg/cg_dst
```

# snapmirror list-destinations

Display a list of destinations for SnapMirror sources

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **snapmirror list-destinations** command displays information including the destination endpoints, the relationship status, and transfer progress, for SnapMirror relationships whose source endpoints are in the current Vserver if you are in a Vserver context, or the current cluster if you are in a cluster context. +

The command might display several relationships that have the same source and destination

endpoints, but have different relationship IDs. If this is the case, some of the information is stale. It corresponds to relationships that have been deleted on the destination Vserver or cluster, and have not been released yet on the source Vserver or source cluster.

The relationships and the information displayed are controlled by the parameters that you specify. If no parameters are specified, the command displays the following information associated with each SnapMirror relationship whose source endpoint is in the current Vserver if you are in a Vserver context, or the current cluster if you are in a cluster context:

- Source path
- Relationship Type
- Destination Path
- Relationship Status
- Transfer Progress
- Progress Last Updated
- Relationship ID

Note the following limitations on the information displayed by the `snapmirror list-destinations` command:

- The **"Relationship Status"** field is not valid after the node hosting the source volume joins the cluster quorum, until at least one transfer is performed on the SnapMirror relationship.
- **"Transfer Progress"** and **"Progress Last Updated"** fields are only valid if a Snapshot copy transfer is in progress.
- The **"Relationship ID"** field is not valid for Vserver SnapMirror relationships.
- The **"Relationship Status"**, **"Transfer Progress"**, and **"Progress Last Updated"** fields are not valid for FlexGroup relationships, but they are valid for FlexGroup constituent relationships.

The `-instance` and `-fields` parameters are mutually exclusive and select the fields that are displayed. The `-instance` parameter if specified, displays detailed information about the relationships. The `-fields` parameter specifies what fields should be displayed. The other parameters of the `snapmirror list-destinations` command, select the SnapMirror relationships for which the information is displayed.

This command is not supported for SnapMirror relationships with non-Data ONTAP endpoints.

## Parameters

`{ [-fields <fieldname>, ... ] }`

If you specify the `-fields <fieldname>, ...` parameter, the command only displays the fields that you have specified.

`[ -instance ] }`

If you specify the `-instance` parameter, the command displays detailed information about all relationships selected.

**{ [-S, -source-path****{<[vserver:][volume]>|<[[cluster:]]//vserver/]volume>|<hostip:/lun/name>|<hostip:/share/share-name>|<[vserver:]/cg/[cgroup]>}} - Source Path**

Selects SnapMirror relationships that have a matching source path name.

**[-source-vserver <vserver name>] - Source Vserver**

Selects SnapMirror relationships that have a matching source Vserver name.

**[-source-volume <volume name>] - Source Volume }**

Selects SnapMirror relationships that have a matching source volume name.

**{ [-destination-path****{<[vserver:][volume]>|<[[cluster:]]//vserver/]volume>|<hostip:/lun/name>|<hostip:/share/share-name>|<[vserver:]/cg/[cgroup]>}} - Destination Path**

Selects SnapMirror relationships that have a matching destination path name.

**[-destination-vserver <vserver name>] - Destination Vserver**

Selects SnapMirror relationships that have a matching destination Vserver name.

**[-destination-volume <volume name>] - Destination Volume }**

Selects SnapMirror relationships that have a matching destination volume name.

**[-relationship-id <UUID>] - Relationship ID**

Selects SnapMirror relationships that have a matching relationship identifier. This parameter is not supported for Vserver SnapMirror relationships.

**[-type <snapmirrorType>] - Relationship Type**

Selects SnapMirror relationships that have a matching relationship type. Possible values are:

- DP
- XDP
- RST

**[-relationship-group-type {none|vserver|consistencygroup|flexgroup|vserverflexgroup}] - Relationship Group Type**

Selects SnapMirror relationships that have a matching relationship group type. Possible values are:

- none
- vserver
- flexgroup

**[-policy-type {vault|async-mirror|mirror-vault|strict-sync-mirror|sync-mirror|automated-failover|continuous}] - SnapMirror Policy Type**

Selects SnapMirror relationships that have a matching SnapMirror policy type. Possible values are:

- async-mirror
- vault

- mirror-vault

**[-cg-item-mappings {<source volume>:@<destination volume>|<source item path>:@<destination item path>}] - Consistency Group Item Mappings**

Selects SnapMirror relationships that have a matching list of Consistency Group (CG) item mappings. This parameter is applicable to CG level relationships only.

**[-status <mirror status>] - Relationship Status**

Selects SnapMirror relationships that have a matching relationship status. Possible values are:

- Idle
- Transferring

This parameter is not supported for FlexGroup SnapMirror relationships, but it is supported for FlexGroup constituent relationships.

**[-transfer-progress {<integer>[KB|MB|GB|TB|PB]}] - Transfer Progress**

Selects SnapMirror relationships that have a matching transfer progress. This parameter is not supported for FlexGroup SnapMirror relationships, but it is supported for FlexGroup constituent relationships.

**[-progress-last-updated <MM/DD HH:MM:SS>] - Timestamp of Last Progress Update**

Selects SnapMirror relationships that have a matching transfer progress last updated timestamp. This parameter is not supported for FlexGroup SnapMirror relationships, but it is supported for FlexGroup constituent relationships.

**[-source-volume-node <nodename>] - Source Volume Node Name**

Selects SnapMirror relationships that have a matching source volume node name. For FlexGroup relationships, it is the node which owns the root constituent source volume. This parameter is not supported for Vserver SnapMirror relationships.

**[-expand <true>] - Show Constituents of the Group**

Specifies whether to display constituent relationships of Vserver and FlexGroup SnapMirror relationships. By default, the constituents are not displayed.

## Examples

To display summary information about all relationships whose source endpoints are in the current cluster, type the following command:

```
cluster1::> snapmirror list-destinations
Progress
Source          Destination      Transfer  Last      Relationship
Path           Type  Path           Status  Progress  Updated   ID
-----
vserver1.example.com:dp_s1
                DP    vserver2.example.com:dp_d1
                                Idle    -         -         06b4327b-954f-11e1-af65-
```

```

123478563412
vserver1.example.com:xdp_s1
      XDP  vserver2.example.com:xdp_d1
              Idle  -      -      a9c1db0b-954f-11e1-af65-
123478563412
vserver2.example.com:
      DP  dvserver2.example2.com:
              Idle  -      -      -
3 entries were displayed.

```

To display summary information about all relationships whose source endpoints are in the current Vserver, type the following command:

```

vserver1.example.com::> snapmirror list-destinations
Progress
Source          Destination          Transfer  Last      Relationship
Path           Type  Path             Status    Progress  Updated   ID
-----
vserver1.example.com:dp_s1
      DP  vserver2.example.com:dp_d1
              Idle  -      -      06b4327b-954f-11e1-af65-
123478563412
vserver1.example.com:xdp_s1
      XDP  vserver2.example.com:xdp_d1
              Idle  -      -      a9c1db0b-954f-11e1-af65-
123478563412
2 entries were displayed.

```

To display detailed information about SnapMirror relationships whose source endpoints are in the current Vserver, type the following command:

```

vserver1.example.com::> snapmirror list-destinations -instance
Source Path: vserver1.example.com:dp_s1
      Destination Path: vserver2.example.com:dp_d1
      Relationship Type: DP
      Relationship Group Type: none
      Relationship Status: Idle
      Transfer Progress: -
      Progress Last Updated: -
      Source Volume Node: node1
      Relationship ID: 06b4327b-954f-11e1-af65-123478563412
Source Path: vserver1.example.com:xdp_s1
      Destination Path: vserver2.example.com:xdp_d1
      Relationship Type: XDP
      Relationship Group Type: none
      Relationship Status: Idle
      Transfer Progress: -
      Progress Last Updated: -

```

```
Source Volume Node: node2
Relationship ID: a9c1db0b-954f-11e1-af65-123478563412
```

2 entries were displayed.

To display summary information about all relationships including constituent relationships whose source endpoints are in the current Vserver, type the following command:

```
cluster-1::> snapmirror list-destinations -expand
```

Source Path	Type	Destination Path	Status	Transfer Progress	Progress Last Updated	Relationship Id
vs1:fg_s1	XDP	vs1:fg_d1	-	-	-	504abc00-70a8-11e6-82be-0050568536d7
vs1:fg_s1__0001	XDP	vs1:fg_d1__0001	-	-	-	5041f2aa-70a8-11e6-82be-0050568536d7
vs1:fg_s1__0002	XDP	vs1:fg_d1__0002	-	-	-	50421733-70a8-11e6-82be-0050568536d7
vs1:fg_s1__0003	XDP	vs1:fg_d1__0003	-	-	-	50421826-70a8-11e6-82be-0050568536d7
vs1:fg_s1__0004	XDP	vs1:fg_d1__0004	-	-	-	504218f0-70a8-11e6-82be-0050568536d7

5 entries were displayed.

## snapmirror modify

Modify a SnapMirror relationship

**Availability:** This command is available to *cluster* and *Vserver* administrators at the *admin* privilege level.

## Description

The **snapmirror modify** command allows you to change one or more properties of SnapMirror relationships. The key parameter that identifies any SnapMirror relationship is the destination endpoint. The destination endpoint can be a Vserver, a volume, or a non-Data ONTAP endpoint.
